GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index is \$90.00, Domestic and \$120.00, Foreign. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)

REVIEW

- 79-1201 Chronic Diarrhea. A Practical Approach.** (Eng) Matseshe, J. W. (Mayo Clinic, Mayo Medical Sch., Rochester, MN); Phillips, S. F. *Med Clin North Am* 62(1): 141-154; 1978.

A practical approach to the diagnosis and treatment of chronic diarrhea is discussed. Chronic diarrhea is an increase in the frequency, fluidity, or volume of bowel movements relative to the usual habits for that individual lasting for > 2 wk or recurring after the initial attack. Evaluation of the patient should include the taking of an adequate history, including character of the current illness; past medical, surgical, and family history; and past history of laxative use. Primary physical examination involves a full examination of all systems and digital rectal, anoscopic, and simple stool examinations. Later tests should include examination of the stool, proctosigmoidoscopy, blood studies, barium enema, and tests for malabsorption and serum hormone levels. Among the specific causes of chronic diarrhea are functional causes, irritable colon, inflammatory bowel disease, carcinoma of the large bowel, amebic colitis, *Giardia lamblia*, metabolic disorders, and gastrointestinal hormone-producing tumors (carcinoid syndrome, Zollinger-Ellison syndrome, pancreatic cholera). Symptomatic treatment is accomplished by replacement of fluids and the administration of appropriate antidiarrheal agents. (33 refs)

- 79-1202 Chemical Carcinogens (3 Letters to Editor).** (Eng) Hooper, N. K. (Dept. Biochemistry, Univ. California, Berkeley, CA, 94720); Harris, R. H.; Ames, B. N.; Schneiderman, M. A. *Science* 203(4381): 602-603; 1979.

Two studies cited in a recent report on chemical carcinogens that support the threshold theory, one concerning vinyl chloride and one concerning chloroform, are criticized. The basic arguments that detoxifying mechanisms are overwhelmed at high dose levels and that high doses of chemicals cause pathological damage to tissues and increase their susceptibility to cancer are countered by other studies showing the opposite results. In addition, a biological model implied in the report--that logarithm of the percent of animals developing a tumor is linearly related to the logarithm of the dose--is inappropriate. (16 refs)

- 79-1203 Chapter 11. Quantitative Risk Assessment.** (Eng) Scientific Committee (Food Safety Council, 221 Teachers Bldg., Columbia, MD, 21044). *Food Cosmet Toxicol* 16(Suppl 2): 109-136; 1978.

Problems involved in quantitatively assessing the risk to humans of food substances implicated in laboratory toxicity,

mutagenicity, and/or carcinogenicity tests are reviewed. The probit, logit, one-hit, gamma multi-hit, Armitage-Doll multi-stage, and the statistico-pharmacokinetic models are discussed, and recommendations are made for a low-dose risk assessment. (38 refs)

- 79-1204 Statistical Design of Toxicity Assays: Role of Genetic Structure of Test Animal Population.** (Eng) Haseman, J. K. (Biometry Branch, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Hoel, D. G. *J Toxicol Environ Health* 5(1): 89-101; 1979.

The statistical aspects of strain-to-strain differences in cancer susceptibility are considered, and one strain vs multistrain testing is discussed. Previous data were examined to evaluate the magnitude of within-study, interstrain differences in tumor induction. Although there was a very high overall association between mouse strains [(C57BL/6 x C3H/Anf)_{F₁} and (C57BL/6 x AKR)_{F₁}] with respect to hepatoma induction, evidence of strain-to-strain variability was found for several compounds; ie, sodium diethyldithiocarbamate, PCNB (quintozene), bis(2-chloroethyl)ether, and potassium bis(2-hydroxyethyl)dithiocarbamate. A survey of several long-term carcinogenicity studies with DDT revealed interstrain differences in cancer susceptibility for this compound also. When data from these DDT studies were used to estimate the risk of cancer in humans, the risk estimates varied widely. Even for studies in which some increased risk was indicated, there was as much as a 1,000-fold difference in the actual risk estimates for lung tumors. Statistical calculations indicate that if susceptible subgroups do exist and if certain simplifying assumptions are made, then in many cases tumor increases can be detected more readily by studying several inbred mouse strains rather than a single outbred stock. (17 refs)

- 79-1205 Short-Term Mutagenicity Tests for Carcinogens--Their Place in Toxicological Evaluation.** (Eng) Bridges, B. (MRC Cell Mutation Unit, Univ. Sussex, Falmer, Brighton BN1 9QG, England). *Invest Cell Pathol* 1(4): 293-295; 1978.

The role of short-term mutagenicity tests for carcinogens in toxicological evaluations for regulatory and decision-making purposes is considered. It has been argued that only the currently established microsome/*Salmonella typhimurium* (Ames) protocol has been validated and that departures from it should be discouraged. However, there is evidence that the liver microsome mix does not always represent the actual balance of activation and detoxification in vivo. It is suggested that the Ames test be supplemented by investigations of

the response of other cellular indicator systems and by studies of the actual balance of metabolism in the whole animals and in a range of different tissues. Such studies could then form a satisfactory basis for regulatory action and company decision-making on substances to which the public may be exposed to a significant extent. The bacteria/microsome test taken on its own does not achieve this goal. (7 refs)

- 79-1206 Chapter 6. Genetic Toxicology.** (Eng) Scientific Committee (Food Safety Council, 221 Teachers Bldg., Columbia, MD, 21044). *Food Cosmet Toxicol* 16(Suppl 2): 35-63; 1978.

The state-of-the-art in the field of mutagenicity testing is reviewed extensively. A detailed discussion of assays for determining mutagenic activity in vitro and in vivo covers the test organisms and the types of mutations investigated. (132 refs)

- 79-1207 Genetic Constitution and Response to Toxic Chemicals--An Overview.** (Eng) Womack, J. E. (Inst. Comparative Medicine, Texas A&M Univ., College Station, TX, 77843). *J Toxicol Environ Health* 5(1): 49-51; 1979.

Information that supports the argument against the use of random-bred or outbred rodents in carcinogenesis and toxicological testing is reviewed. There is no scientific justification for this practice. The frequent desire for heterozygosity in a test population can best be met by using F₁ hybrids of inbred progenitor strains. (5 refs)

- 79-1208 Genetic Aspects of Metabolic Processing of Chemical Substances.** (Eng) Thorgeirsson, S. S. (Biochemical Pharmacology Section, Lab. Chemical Pharmacology, NCI, NIH, Bethesda, MD, 20014); Wirth, P. J. *J Toxicol Environ Health* 5(1): 83-87; 1979.

Studies of the *Ah* locus in the mouse, which controls the induction of cytochrome P₁-450 and at least 10 associated monooxygenase activities, are reviewed. A single gene difference has been shown to exist between the inbred mouse strains C57BL/6N and DBA/2N in the induction of aryl hydrocarbon hydroxylase, a hepatic monooxygenase activity, and cytochrome P₁-450 (P-448) by 3-methylcholanthrene (3-MC). Studies using > 30 inbred mouse strains indicate that two-thirds are genetically responsive and about one-third are nonresponsive. Numerous other monooxygenase activities are induced by 3-MC; this induction is closely associated with the *Ah-b* allele. Differences at the *Ah* locus have been related to differences in survival time in mice given massive doses of benzo(a)pyrene, 7,12-dimethylbenz(a)anthracene, hexachlorocyclohexane (lindane), or polychlorinated biphenyls. In these cases, the survival time of the responsive strains was significantly shorter than that of the nonresponsive inbred strains. The *Ah-b* allele is also highly correlated with

acetaminophene (AAP)-induced glutathione depletion, hepatotoxicity, and increases in covalently bound AAP metabolites. Large doses of 2-acetylaminofluorene, unlike AAP, do not cause hepatic glutathione depletion, even though similar large increases were observed in the rate of N-hydroxylation of both drugs after induction of cytochrome P₁-450 by 3-MC. (16 refs)

- 79-1209 Genetic Toxicology of Bleomycin.** (Eng) Vig, B. K. (Nevada Mental Health Inst., P.O. Box 2460, Reno, NV, 89505); Lewis, R. *Mutat Res* 55(2): 121-145; 1978.

Data on the genetic toxicology of bleomycin, a class of approx 200 antibiotic compounds that differ from each other in the amine moiety, are reviewed. At low concentrations, the drugs can cause elimination of bases, particularly thymine. This results in DNA strand breakage and inhibition of cell growth, although the two effects may not be related. In general, mitotically dividing cells, especially those in G₂, are most sensitive to DNA damage, indicating that cell death may not be related to a direct effect of the antibiotic on DNA replication. The drugs cause chromosomal damage in all subphases of interphase, and they can also affect early prophase chromosomes. Bleomycin-induced breakage and cell death may be similar to those induced by densely ionizing radiations. Whereas the antibiotics affect the frequency of somatic crossing-over and produce micronuclei, the data on mutation induction and production of sister chromatic exchanges do not permit classification of the bleomycins as potent inducers of these phenomena. The genetic effects of the bleomycins can be quantitatively modified by thiol compounds, caffeine, hyperthermia, and H₂O₂. The available data do not permit assessment of genetic damage in the offspring of bleomycin-treated patients. Studies of these effects are needed, as are studies to determine the effects of bleomycins on meiosis. (130 refs)

- 79-1210 Chemical Modifications of DNA Conformation.** (Fre) Daune, M. (Laboratoire de Biophysique, Institut de Biologie Moléculaire et Cellulaire, CNRS, 15 rue Rene Descartes, 67000 Strasbourg, France). *Biochimie* 60(10): 1097-1110; 1978.

The mechanisms by which three classes of chemical carcinogens (alkylating agents, aromatic hydrocarbons, and aromatic amines) alter DNA are reviewed. It is assumed that chemical carcinogenesis occurs when a chemical agent causes a change in DNA that is perpetuated and translated into genetic deprogramming and tissue alteration. The first step in chemical carcinogenesis is fixation of a metabolite of the chemical to the DNA molecule. The structural alteration that follows can then disturb replication, transcription, or DNA repair. The methods by which biological systems repair DNA lesions induced by chemical carcinogens are described. The limitations of present knowledge of the mechanisms of chemical carcinogenesis and DNA repair are considered. (62 refs)

- 79-1211 **Studies of the Relationships Between Mutagenesis and Carcinogenesis.** (Fre) Hofnung, M. J. (Unite de Toxicologie genetique, Institut Pasteur, Paris, France). *Biochimie* 60(10): 1151-1171; 1978.

Studies of the relationship between mutagenesis and carcinogenesis are reviewed. A linear relationship was found between the dose inducing tumors in experimental animals and that inducing revertants in *Salmonella typhimurium* for aflatoxin B₁, sterigmatocystin, benzo(a)pyrene, propane sulfone, dibenz(a,h)anthracene, 4-aminobiphenyl, benzidine, and 2-naphthylamine. However, there is no direct proof of a relationship between mutagenesis and carcinogenesis. (16 refs)

- 79-1212 **Mutagens and Carcinogens.** (Eng) Brookes, P. (Chemical Carcinogenesis Div., Inst. Cancer Res., Pollards Wood Res. Station, Chalfont St. Giles, Bucks, England). *Invest Cell Pathol* 1(4): 291-293; 1978.

The relationship between mutagens and carcinogens is briefly considered. The use of radioactively labeled carcinogens led to the finding that they were bound to the DNA of treated cells. Although much of the administered carcinogen was eliminated following metabolism, a small percentage was converted to a chemically reactive form that could penetrate the nucleus and interact with DNA. The mutation theory of cancer would, therefore, predict that all ultimate carcinogens should be mutagenic, which has proved true. Several observations are consistent with the view that cancer results from a mutational event. These include epidemiological studies of childhood tumors and cell hybridization studies with normal and tumor cells. Many tumors in animals and humans are clonal. The discovery that cells from the skin of patients with xeroderma pigmentosum and ataxia telangiectasia are defective in the repair of DNA damage induced by radiation or chemicals, is strongly indicative of the role of DNA modification in cancer causation. (15 refs)

- 79-1213 **Evidence in the Experimental Animal of the Mutagenic Properties of Chemical Agents.** (Fre) Siou, G. (Laboratoire d'Histopathologie, C.E.R.T.I., 88, avenue de Paris, 78000 Versailles, France); Conan, L. *Ann Falsif Expt Chim* 71(770): 411-426; 1978.

Methods of detecting the mutagenic potential of chemical agents in laboratory mammals are reviewed. Chemicals that have proved mutagenic effects on blood and germ cells are tabulated. Results of in vivo and in vitro mutagenicity tests of six chemicals (benzomyl, methylbenzimidazole carbamate, phosphamidon, polyvinyl chloride, diquat, and captane) are compared. (55 refs)

- 79-1214 **Cocarcinogenic or Conditional Cancer-promoting Factors: New Aspects of the Etiology of Human Tumors and Molecular Mechanisms of Tumor Development.** (Ger) Hecker, E. (Institut für Biochemie, Deutsches

Krebsforschungszentrum, D-6900 Heidelberg, W. Germany). *Naturwissenschaften* 65(12): 640-648; 1978.

Findings during the last 10 yr on the sources of exogenous cocarcinogens and their mode of action are reviewed. In the mouse epidermis model, a single dose of carcinogen produces no tumors; if several doses of cocarcinogen follow, many benign tumors result. Some of these tumors progress to malignancy, possibly under the influence of a postulated progressor substance. This sequence is the basis of the "three-step" model of cancer development. Within the last 10 yr, numerous exogenous cocarcinogens were identified chemically and biologically and characterized as tumor initiators or promoters. They are the highly irritant diterpene (DTP) esters (ie, tiglliane, daphnane, and ingenane) from Euphorbiaceae and Thymelaeaceae plants. Many of these plants have long been used as teas, folk medicines, cleaning agents, or insect repellants. The high incidence of esophageal cancer among natives of Caracao has been traced to their extensive use of the Euphorbiaceae *Croton flavens*. Chemical studies have shown that the variation in the cocarcinogenicity of DTP's depends on the presence of side chains. Some DTP's (cryptic cocarcinogens) are inactive unless substituents are removed; after enzymatic action, they become cocarcinogenic. Not all DTP's that are skin irritants are cocarcinogens. Cocarcinogens increase DNA synthesis. The promoting effect of different DTP's correlates positively with the in vitro release of prostaglandin E₂ from mouse skin. These cocarcinogens also can induce virus synthesis in cells containing persistent genomes by simian virus 40 or Epstein-Barr virus. (45 refs)

- 79-1215 **Report of the Workshop on Carcinogenicity.** (Eng) Butler, W. H. (Safety Medicines Dept., Pathology Section, Imperial Chemical Industries, Ltd., Alderley Park, Macclesfield, Cheshire, England). *J Toxicol Environ Health* 5(1): 161-162; 1979.

Information presented at a workshop on the choice of animals for carcinogenicity testing is summarized briefly. Topics covered include the use of inbred vs outbred animals, the comparative influence of genetic and environmental determinants in modifying the behavior of the animal, selecting a species or strain for a specific purpose, and current regulations for carcinogenicity testing. (no refs)

- 79-1216 **Alpha-Fetoprotein as an Indicator of Early Events in Chemical Carcinogenesis.** (Eng) Sell, S. (Dept. Pathology, M-012, Univ. California at San Diego, La Jolla, CA, 92093). *ACS Symp Ser* 80: 326-341; 1978.

Properties of α -fetoprotein (AFP), its synthesis and levels during normal development, and its significance in hepatotoxic liver injury and in tumor growth and development are reviewed. It has been hypothesized that AFP acts as a signal for the organization of liver tissue into normal lobules during normal growth or regeneration. According to this hypothesis, AFP production during exposure to hepatocarcinogens

represents an inappropriate signal. Carcinogens induce a small number of immature hepatocytes (possibly stem cells) to proliferate. Under inappropriate signals for organization, some of these stem cells, perhaps only one or two per liver, eventually produce hepatocellular carcinomas. The previously accepted sequential evolution of hepatocellular carcinomas from foci of altered hepatocytes through neoplastic nodules to malignant tumors is not supported by the results of ongoing experiments. Neoplastic nodules may represent a noncancerous response of differentiated hepatocytes to carcinogen exposure. (75 refs)

- 79-1217 A Review of the Specifications and Toxicity of Synthetic Food Colors Permitted in Canada.** (Eng) Khera, K. S. (Natl. Health and Welfare Canada, Ottawa, Ontario, Canada); Munro, I. C. *CRC Crit Rev Toxicol* 6(2): 81-133; 1979.

The chemical and biological characteristics of food dyes that relate to their safety evaluation are reviewed in detail, with emphasis on those dyes whose use is permitted in Canada. These dyes include amaranth, Ponceau SX, Sunset Yellow FCF, and Citrus Red No. 2 from the azo category; tartrazine from the azopyrazolone dyes; Brilliant Blue FCF and Fast Green FCF from the triphenylmethanes; erythrosin from the xanthenes; and indigotin from the indigoid class. (608 refs)

- 79-1218 Carcinogens in Food and the Delaney Clause.** (Eng) Jukes, T. H. (Div. Medical Physics, Univ. California, Berkeley, CA, 94720). *JAMA* 241(6): 617-619; 1979.

The Delaney Clause, a statement in the Food Additives Amendment of the Federal Food, Drug, and Cosmetic Act that became a law in 1958, prohibits the addition of any substance to food that causes cancer in humans or animals. The clause does not recognize and exempt a no-effect level of a carcinogen. Many carcinogens in food, however, are from natural sources. In addition to aflatoxin, other substances in molds, such as patulin (found in 37% of apple juice samples examined by the FDA), are carcinogenic. Nitrite, which some experiments suggest is carcinogenic, is added to meat products. However, <20% of the nitrite intake is from that added to meat and >80% is in saliva, where it is produced by the action of oral bacteria on nitrates that occur in vegetables. Nitrites also react with secondary amines to produce nitrosamines, which are carcinogenic in various animals. Secondary amines of natural origin, eg, proline, occur widely in foods. Pyrolysis produces benzo(a)pyrene in many foods, including roasted coffee and smoked meats. Man-made substances such as pesticides or diethylstilbestrol (DES) may also enter the food supply. Viewed against the background of endogenous estrogen production, the effect of the max probable intake of DES from beef is inconsequential. It is concluded that the existence of the Delaney Clause has focused attention on certain food additives, but nonadditive carcinogenic substances in food may be ignored. Regulatory distinctions should not

be drawn between various carcinogens on the basis of whether they are natural or man-made. (20 refs)

- 79-1219 The Detection and Control of Mutagenic and Carcinogenic Compounds in the Environment.** (Eng) Ramel, C. (Environmental Toxicology Unit, Wallenberg Lab., Univ. Stockholm, S-104 05 Stockholm, Sweden). *Ambio* 7(5/6): 244-249; 1978.

A sequential, tiered system of mutagenicity screening is proposed as the only feasible means of identifying genotoxic substances in the environment. The suggested system comprises three levels (detection, verification, and quantification) and it should lead to a useful risk-benefit analysis of the compound under investigation. (55 refs)

- 79-1220 The Role of Insects and Other Plant Pests in Aflatoxin Contamination of Corn, Cotton, and Peanuts--A Review.** (Eng) Widstrom, N. W. (US Dept. Agriculture-SEA, Tifton, GA). *J Environ Qual* 8(1): 5-11; 1979.

The involvement of insects in the fungal infection of agricultural products and the subsequent development and production of aflatoxins is reviewed. The principal role of insects in toxin contamination is one of predisposing plant tissue to fungus invasion. There is no conclusive evidence linking the pests of peanuts with aflatoxin contamination of that crop. (62 refs)

- 79-1221 Status of the Aflatoxin Problem in Corn.** (Eng) Zuber, M. S. (Univ. Missouri-Columbia, Columbia, MO); Lillehoj, E. B. *J Environ Qual* 8(1): 1-5; 1979.

Information concerning aflatoxin contamination of corn, effects of the environment on aflatoxin levels, and methods of controlling this contamination are reviewed. Conditions in the southern US are more conducive to fungal infection and subsequent toxin production. Insects and stress conditions, such as drought, enhance the problem. A break in the pericarp is necessary for fungal invasion. The use of insect-resistant hybrids and practices that reduce stress or shift the ear development stage to miss a likely stress period are recommended. (24 refs)

- 79-1222 Bran and Experimental Colon Cancer (4 Letters to Editor).** (Eng) Newcombe, R. G. (Dept. Medical Statistics, Welsh Natl. Sch. Medicine, Heath Park, Cardiff CF4 4XN, Wales). *Lancet* 1(8107): 108; 1979.

Two previous studies, one showing a protective effect of dietary fiber against 1,2-dimethylhydrazine (DMH)-induced rat colonic cancer and the other showing no effect, are discussed. Although the former study has been justifiably criticized, the latter cannot be taken as strong evidence against a protective

effect in humans. The relevance to human carcinogenesis of the DMH animal model is questionable. A model using a strain bred for very high natural cancer risk would be more realistic. (9 refs)

- 79-1223 Polybrominated Biphenyls.** (Eng) IARC Working Group (Lyon, France). In: *IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans: Polychlorinated Biphenyls and Polybrominated Biphenyls*. International Agency for Research on Cancer. (Lyon, France): 18: 107-124; 1978.

The chemical and physical data; production, use, occurrence, and analysis; and biological data relevant to the evaluation of carcinogenic risk to humans are presented for the polybrominated biphenyls (PBB's) hexabromobiphenyl (HBB), octabromobiphenyl, and decabromobiphenyl. The experimental carcinogenicity data consist of only one experiment with a commercial preparation of HBB, Firemaster FF-1. It was tested in rats by po administration of single doses. Although neoplastic changes of the liver were reported, the study was considered inadequate. Firemaster FF-1 is embryotoxic and teratogenic. Cytogenetic tests in mice were negative. No case reports or epidemiological studies of humans were available for any of the PBB's. The extensive production of PBB's, their persistence in the environment and in the body, and their use, mainly as flame retardants, indicate that widespread human exposure occurs. No evaluation of the carcinogenicity of PBB's could be made on the basis of available data. (57 refs)

- 79-1224 Polychlorinated Biphenyls.** (Eng) IARC Working Group (Lyon, France). In: *IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans: Polychlorinated Biphenyls and Polybrominated Biphenyls*. International Agency for Research on Cancer. (Lyon, France): 18: 43-103; 1978.

A critical review of carcinogenicity data for 39 polychlorinated biphenyls (PCB's) is presented in terms of human risk. Experimental data showed that Kanechlor 500 and Aroclor 1254 are carcinogenic in mice and that Aroclor 1260 is carcinogenic in rats; all induced benign and malignant liver cell tumors. Kanechlor 300, 400, and 500 induced liver lesions described as multiple hyperplastic nodules. Human exposure to small amounts of PCB's is widespread as a result of environmental contamination and the high stability of these compounds. Epidemiological data provide suggestive evidence of a relationship between exposure to PCB's and the development of malignant melanoma. Further data are needed to confirm these relationships, but in the meantime, PCB's should be regarded as if they were carcinogenic to humans. Almost without exception, PCB's contain various levels of polychlorinated dibenzofurans (PCD's) as contaminants. It is not known if and to what extent PCD's play a role in the observed carcinogenic effects of PCB's. (236 refs)

- 79-1225 Polychlorinated Dibenzodioxins and Dibenzofurans--Compounds of Current Interest.**

(Swe) Rappe, C. (Dept. Organic Chemistry, Umea Univ., S-901 87 Umea, Sweden). *Lakartidningen* 16(1/2): 21-24; 1979.

Recent studies of the toxicology of dioxins and dibenzofurans are reviewed. 2,3,7,8-Tetrachlorodioxin was found to be a potent carcinogen in experimental animals, even in small doses. 1,2,3,6,7,8-hexachlorodibenzodioxin and 1,2,3,7,8,9-hexachlorodibenzodioxin also induced tumors in experimental animals. No pronounced organ specificity was found for these compounds. Polychlorinated dibenzodioxins and dibenzofurans occur as impurities in technical products such as 2,4,5-trichlorophenol and chlorinated phenols in general, and they are formed in pyrolytic reactions as well. Exposure to these carcinogens is highest in the production of (2,4,5-trichlorophenoxy)acetic acid and other chlorophenols. An epidemiological case-control study revealed an increased incidence of malignant mesenchymal soft-tissue tumors in persons exposed to phenoxy acids and chlorophenols. The tumors may be due to these substances and/or the impurities they contain. (45 refs)

- 79-1226 Concentrations of Polycyclic Aromatic Hydrocarbons in the Workplace.** (Ger) Otto, J. (Arbeitshygieneinspektion des Rates des Bezirkes Erfurt, Predigerstrasse 6, DDR-50 Erfurt, E. Germany); Schmidt, E. *Z Gesamte Hyg* 24(12): 896-898; 1978.

Polycyclic aromatic hydrocarbon levels in work areas in which carbon black is processed in the rubber industry, tar is processed, and combustion engines are used in enclosed spaces were determined by gas chromatography in the temperature range of 298-495 C. The highest levels were found in tar-processing areas (up to 29 $\mu\text{g}/\text{m}^3$). In areas involving carbon black and exhaust gas exposure, they were as high as 2.4 and 8 $\mu\text{g}/\text{m}^3$, respectively, with benzo(a)fluorene, benzo(a)anthracene, and benzo(a)pyrene predominating. (19 refs)

- 79-1227 Epithelial Cancer, Differentiation, and Vitamin A.** (Eng) Hogan, B. (Imperial Cancer Res. Fund Labs., Mill Hill, London, England). *Nature* 277(5694): 261-262; 1979.

The effects of retinoids, a class of compounds based on vitamin A, on epithelial cells in organ culture, on epithelial carcinogenesis in vivo, and on cultures of transformed and untransformed cells are reviewed. Several reports show that feeding animals high doses of retinoids, especially retinoic acid, after carcinogen treatment reduces the severity and incidence of lesions in a variety of epithelial sites (bladder, lung, and trachea). Retinoids seem to act like antipromoters, although in certain systems they have been found to act like promoters. (15 refs)

- 79-1228 Diethylstilbestrol and the Risk of Cancer (2 Letters to Editor).** (Eng) Clark, L. C. (Univ. North Carolina, Chapel Hill, NC, 27514); Portier, K. M.; Bibbo, M.; Haenszel, W. M.; Wied, G. L.; Hubby, M.; Herbst, A. L. *N Engl J Med* 300(5): 263-264; 1979.

The results of two studies in which it was concluded that diethylstilbestrol (DES) therapy does not increase cancer risk are reevaluated. A chi-square analysis of the cancer mortality data from one study indicates that DES exposure is associated with more than a twofold increase in risk for all cancers; the risk increases to 2.73 for endocrine-related tumors and to 2.89 for breast cancer. Both studies lack the statistical power to justify the conclusion that DES does not increase cancer risk. Presentation of the data with both the point estimate of risk and its associated confidence interval would aid in proper interpretation of the study results. The difference in the magnitude of relative risk between the incidence and mortality cases may be due to differences in risk between premenopausal and postmenopausal breast cancer or to the fact that mean latency is better represented by the mortality cases than by the incidence cases. In a reply, the authors of one study state that point estimates and their confidence limits were considered in reaching conclusions. The statement that mean latency is better represented by mortality cases has little foundation in any carcinogenesis models. The critics disregard the excess risk for breast cancer in the entire study group and the absence of a gradient risk for the DES-exposed women starting therapy by the 11th week, compared with those who started later. Another troublesome point is that excess risk in the premenopausal ages has not been reproduced among the postmenopausal women. These results led to the suggestion, in the original article, that the selection of mothers entering the randomized clinical trial might be a confounding factor. (3 refs)

- 79-1229 Pathology of Prenatal Diethylstilbestrol Exposure.** (Eng) Welch, W. R. (No affiliation given); Prat, J.; Robboy, S. J.; Herbst, A. L. *Pathol Annu* 13(1): 201-216; 1978.

Studies of the association between prenatal diethylstilbestrol (DES) exposure and clear cell adenocarcinoma (CCA) of the vagina or cervix are reviewed. Of > 350 cases reported to the Registry for Research on Hormonal Transplacental Carcinogenesis as of June 1977, prenatal exposure to DES or to the related nonsteroidal estrogens dienestrol or hexestrol was documented in 60%. The youngest patient was 7 yr old at the time of diagnosis and the oldest 28. Microscopically, the CCA associated with DES exposure is identical to CCA of the ovary or endometrium observed in older women. The microscopic differential diagnosis of CCA includes hyperplasia of vestigial mesonephric ducts, Arias-Stella reaction, microglandular hyperplasia, and endodermal sinus tumor. Fifty-six patients with follow-up have developed recurrences or have died. In contrast to squamous cell carcinoma of the vagina or cervix, CCA more often metastasizes to the lung or supraclavicular lymph nodes. Almost every patient in whom the tumor was detected at an asymptomatic stage is

alive and free of disease after initial therapy. The benign abnormalities that occur in 20%-95% of exposed women consist of structural malformations of the vagina and/or cervix and glandular epithelium in the vagina (adenosis) or cervix (ectropion). It is not known whether adenosis is the precursor of the CCA. However, since it has been found in > 90% of the vaginal tumors, it appears to provide the background from which the neoplasm arises. Nonmalignant abnormalities have been reported in men exposed to DES in utero. (33 refs)

- 79-1230 Toxic Agents Resulting From the Oxidative Metabolism of Steroid Hormones and Drugs.** (Eng) Horning, E. C. (Inst. Lipid Res., Baylor Coll. Medicine, Houston, TX, 77030); Thenot, J. P.; Helton, E. D. *J Toxicol Environ Health* 4(2/3): 341-361; 1978.

Mechanisms by which toxic agents result from the oxidative metabolism of steroid hormones and drugs are reviewed. The emphasis is on the structure, mode of formation, and reaction of reactive metabolites of compounds that are related to estrogenic hormones and that are known carcinogens or are associated with cancer in animal models or in humans. The types of structures and reactions included are those arising from (1) the epoxide/dihydrodiol pathway, with an epoxide as the reactive metabolite and with a postulated ionic reaction mechanism for reaction with cell components; (2) the catechol/o-quinone pathway, with an o-quinone as the reactive metabolite and with either an ionic or a neutral semiquinone radical reaction mechanism; and (3) alkylation reactions, in which a radical may be the intermediate species. The possible formation of electrophiles from diethylstilbestrol, natural estrogens, and ethinyl estradiol is discussed in terms of protein binding. Protein binding is presumptive evidence of electrophil formation, but it does not necessarily indicate that the parent compound is highly cytotoxic, mutagenic, or carcinogenic. Mutagenic and carcinogenic activity is presumed to require reaction of an electrophile with nuclear material. There is evidence for protein binding of the above estrogens as a consequence of oxidative metabolism. (71 refs)

- 79-1231 Toxins and Carcinogens in the Environment: An Observation in the Tropics.** (Eng) Bababunmi, E. A. (Dept. Biochemistry, Sch. Medicine, Univ. Ibadan, Ibadan, Nigeria). *J Toxicol Environ Health* 4(5/6): 691-699; 1978.

Reports on the presence of toxic chemicals in the foods and environment of tropical African countries, particularly Nigeria, are reviewed. The incidence of primary liver cancer in these countries is the highest in the world, possibly due to a multiple chemical factor etiology. Toxins identified so far include hypoglycin, dioscorine, sapotoxin, cycasin (a cycad diet has induced malignant tumors of the liver in a number of species), mushroom toxin, capsaicin (red pepper toxin), halogeton toxin (oxalic acid), cyanogen (prussic acid), fluorooleic acid, and some N-nitroso compounds, such as dime-

thyl nitrosamine and diethylnitrosamine, which have been detected in several alcoholic beverages. The fungal contaminants aflatoxin and palmotoxin have been identified on a variety of foodstuffs. Some plants from which herbal teas are brewed contain carcinogens, some of which are pyrrolizidine alkaloids. The emergence of some African countries from the underdeveloped to the developing state has resulted in the introduction of foreign toxic chemicals in such forms as medicine, pesticides, and food additives; ie, quinine, DDT, and cyclamates. (27 refs)

- 79-1232 Carcinogenic Substances in Water.** (Cze) Bartacek, J. (Katedra technologie vody a prostredi, VSCHT, Prague, Czechoslovakia). *Vys SK Chem Technol Praze* 22: 5-49; 1978.

Studies of the occurrence, elimination, and determination of carcinogens in various types of water are reviewed, with special regard to polycyclic aromatic hydrocarbons (PAH). The major PAH's found in water include benzo(a)pyrene, benzo(e)pyrene, anthracene, benz(a)anthracene, 9,10-dimethylbenz(a)anthracene, dibenz(a,h)anthracene, phenanthrene, chrysene, pyrene, fluoranthene, perylene, and 3-methylcholanthrene. Benzo(a)pyrene concentrations of 2-1,000 mg/m³ were found in effluents from coking and petrochemical plants. The PAH content in drinking water can be reduced by ozonation, chlorination, and UV irradiation. (321 refs)

- 79-1233 Some Aspects on the Dosimetry of the Carcinogenic Potency of Asbestos and Other Fibrous Dusts.** (Eng) Pott, F. (Dusseldorf, W. Germany). *Staub-Reinhalt Luft* 38(12): 486-490; 1978.

Factors related to the dosimetry of carcinogenic fibrous dusts are discussed. Length and diameter are among the most important factors related to the dosimetry of fiber carcinogenicity. It is hypothesized that there exists a gradual transition from the noncarcinogenic fiber length or diameter to the fiber length or diameter that possesses max fiber carcinogenicity. In studies in which rats were injected ip with 13 different fibrous dusts, tumor incidence depended on the fiber number in most cases. However, with milled chrysotile A, there was no obvious correlation with fiber number and there was an overall low incidence of tumors with no asbestosis. Human studies have also shown that asbestosis is not a necessary predisposing condition for carcinogenicity, indicating that asbestosis is caused by fibers of different sizes than those that cause tumors or that tumor induction requires fewer fibers than those that cause asbestosis. Other than fiber length and diameter, aerodynamic diameter, irregularities in form, solubility, and the possibility of splitting or breaking should be considered in evaluating fiber carcinogenicity. (27 refs)

- 79-1234 Dust Diseases of the Lungs: Part 2.** (Eng) Longley, E. O. (Worker's Compensation Board--Dust

Diseases, Sydney, Australia). *Med J Aust* 2(10): 474-476; 1978.

Information concerning asbestosis and byssinosis is reviewed. The discussion of asbestosis includes pleural plaque formation and calcification, symptoms and signs, radiological changes, differential diagnosis, and the relationship between asbestosis and bronchogenic carcinoma, mesothelioma, and desquamative interstitial pneumonitis. Byssinosis is characterized by dyspnea and chronic cough associated with cotton flax and hemp occupations. Its diagnosis is discussed. (1 ref)

- 79-1235 Underground Mines and Diesels--The Health and Safety Aspects.** (Eng) Wenberg, R. V. (No affiliation given). *Am Min Congr J* 65(1): 21-25; 1979.

Cancer risk in persons who work in mines in which diesel equipment is used is discussed. No data implicating diesel exhaust as a carcinogenic agent in humans or animals exist. Numerous studies have shown that the levels of NO₂ found in mines in which diesel equipment is used are <5 ppm, the current government standard. (4 refs)

- 79-1236 The Relation of Repair Phenomena to Mutation Induction in Bacteria.** (Eng) Kimball, R. F. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830). *Mutat Res* 55(2): 85-120; 1978.

The role of enzyme systems involved in DNA repair, replication, and recombination in the induction of mutations in bacteria by physical and chemical agents is reviewed. Many enzymatic processes can repair potentially lethal or mutagenic lesions in DNA before these lesions can be converted to final mutations. These processes range in complexity from simple reunion of strand breaks by DNA ligase to multistep processes such as those involved in the excision of pyrimidine dimers. Repair can also remove potentially lethal lesions at the expense of creating premutational lesions or final mutations. A number of mutagens, including UV light, ionizing radiation, and several chemicals, induce an error-prone process, perhaps a modification of the proofreading system, that allows bacteria to survive after potentially lethal damage at the expense of making errors. Some mutagens, notably, monofunctional alkylating agents and base analogs, produce mutations by other processes. Even in these cases, repair processes play an important role. There is some evidence that error-free as well as error-prone repair processes can be induced. For example, growth of bacteria in the presence of low concentrations of alkylating agents can cause resistance to the lethal and mutagenic effects of high-concentration, acute exposures. The relation of these findings to the practical problem of hazards estimations is discussed. (244 refs)

- 79-1237 Replication of Chemically Modified DNA.** (Eng) Villani, G. (Departement de Biologie Moleculaire, Universite Libre de Bruxelles, B-1640 Rhode

St., Genese, Belgium); Spadari, S.; Boiteux, S.; Defais, M.; Caillet-Fauquet, P.; Radman, M. *Biochimie* 60(10): 1145-1150; 1978.

A hypothesis concerning the replication of chemically modified DNA and its relation to mutagenesis is proposed based on a number of published studies. The data indicate that UV photo-products, probably pyrimidine dimers, block, at least temporarily, the continuous progress of the DNA replication complex in bacteria and in mammalian cells. The dose response of the inhibition of DNA synthesis suggests that each pyrimidine dimer is both an absolute block to polynucleotide chain elongation in vitro and a lethal hit in vivo. A 3' to 5' exonuclease has been purified that can arrest DNA synthesis by purified α polymerase on damaged templates. It is hypothesized that this exonuclease is a true proofreading exonuclease with biological functions analogous to those of the polymerase-associated 3' to 5' exonuclease of *Escherichia coli*. Recent findings that mutagenesis of both intact and UV-irradiated herpesvirus can be triggered by UV irradiation of the host cell support the idea that induced mutagenesis in mammalian cells could be a genetically controlled process involving the activity of the proofreading exonuclease. (41 refs)

79-1238 DNA Repair Defects in Genetic Diseases in Man. (Eng) Bootsma, D. (Dept. Cell Biology and Genetics, Erasmus Univ., Rotterdam, Netherlands). *Biochimie* 60(10): 1173-1174; 1978.

Several genetic diseases are associated with defects in DNA repair. The mutation in xeroderma pigmentosum affects an excision repair process involved in the removal of UV-induced pyrimidine dimers. A reduced rate of excision of γ -ray-induced DNA base lesions has been observed in a large number of ataxia telangiectasia patients. In Fanconi's anemia, a defect in repair of DNA interstrand crosslinks and closely spaced overlapping damage is indicated. Bloom's syndrome, although showing a high rate of sister chromatid exchange, has not been shown to be defective in DNA repair. (16 refs)

79-1239 Sun, Light and Human Health. (Eng) Henderson, J. S. (Dept. Pathology, Faculty Medicine, Univ. Manitoba, Winnipeg, Manitoba, Canada R3E 0W3); Jenks, I. H. *Photochem Photobiol* 29(1): 1-5; 1979.

The relationship between sunlight and various diseases, including skin cancer, lupus erythematosus, and the porphyrias, is surveyed briefly, along with interactions between sunlight and the ozone layer and between sunlight and air pollution. (no refs)

79-1240 What Is the Misunderstanding All About (3 Letters to Editor)? (Eng) Cohen, B. L. (No affiliation given); Morgan, K. Z.; Rotblat, J. *Bull At Sci* 35(2): 53-59; 1979.

Two previous articles indicating that the carcinogenicity of low-level radiation is much higher than had been previously believed are criticized, and the authors' responses are presented. (7 refs)

79-1241 Adult Leukemia Following Diagnostic X-Rays? (Eng) Boice, J. D. (Environmental Epidemiology Branch, NCI, Room 3C-07, Landow Building, Bethesda, MD, 20014); Land, C. E. *Am J Public Health* 69(2): 137-145; 1979.

A recent study (by Bross et al) employing a new statistical methodology to reanalyze data from a tristate (New York, Maryland, and Minnesota) leukemia study is reviewed. The Bross report indicated that adult leukemia was related to diagnostic x-ray skin doses between 0.1 and 10 rads, and that previous risk estimates underestimate radiation hazards by a factor of 10. It is felt that the conclusion of the article (that a dose-effect curve was demonstrated in the 1-rad range) is not justified by the analysis or data reported. Although other studies have reported a possible association between a small percentage of adult myeloid leukemia and diagnostic radiation, the risk of myeloid leukemia appeared to be concentrated among subjects receiving unusually large numbers of examinations, and the association may have been indirect rather than causal. The results of radiation-induced leukemia studies and studies referenced by Bross are controversial with respect to interpretation. The Bross paper stretched the data far beyond reasonable limits to produce unwarranted conclusions. The new statistical methodology used in the study depended on a model that was far too complex to be useful. It is doubtful that the model was a reasonable representation of the relationship between radiation dose and leukemia risk. Furthermore, in contrast to the interpretation of Bross et al, the shape of the purported dose-response curve implies that low-dose radiation has less effect per rad than high-dose radiation and that linearity overestimates the risk of radiation exposure at low doses. In conclusion, the Bross et al analysis does not indicate that the risk of low-level radiation exposure is greater than that currently accepted. (69 refs)

79-1242 The Hazards of Fallout or of Epidemiologic Research? (Eng) Land, C. E. (NCI, Bethesda, MD, 20014). *N Engl J Med* 300(8): 431-432; 1979.

The results of a recent study indicating an increased risk of leukemia in children born in "high fallout" rural Utah counties during the period of active nuclear weapon testing must be interpreted carefully. Not only was the control group chosen from different time periods, but it was drawn from "low fallout" counties that are largely urban. Furthermore, mortality for these same high-risk children from cancers other than leukemia is inordinately low, suggesting the possibility of a purely fortuitous association. (3 refs)

79-1243 Recurrent Osteoblastoma: A Review. (Eng) Jackson, R. P. (Dept. Surgery, Univ. Kansas Medical Center Coll. Health Sciences and Hosp., 39th and Rainbow Blvd., Kansas City, KS, 66103). *Clin Orthop* (131): 229-233; 1978.

Three new and 181 previously reported osteoblastomas are reviewed. Eighteen recurrences were found in the 184 cases, more commonly in the spine and pelvis than in other sites. Recurrences were reported as long as 9 yr after excision, indicating the need for long-term follow-up of this lesion. No recurrence has been reported after complete en block resection. Postoperative irradiation does not appear to prevent recurrence of incompletely excised lesions. Five of the recurrences underwent apparent sarcomatous change. In 3/5 sarcomas, the period from initial treatment to diagnosis of malignancy was 6-10 yr; this information was not given in the other two cases. Four of the five sarcomas developed in patients who had received radiotherapy after incomplete excisions. The other sarcoma developed in a patient who had not been irradiated. These results indicate that radiotherapy is not effective in preventing recurrence of osteoblastoma and may possibly be associated with late sarcomatous change in some cases. (14 refs)

79-1244 Ionizing Radiation and Human Breast Cancer. (Eng) Feig, S. A. (Dept. Radiology, Thomas Jefferson Univ. Hosp., Philadelphia, PA). *CRC Crit Rev Diagn Imaging* 11(2): 145-166; 1978.

Epidemiological studies of radiation-related breast cancers in women are reviewed. Four groups of women were included in the studies: (1) Japanese women exposed to atomic bomb gamma; (2) women from Rochester, New York, treated with radiation for postpartum mastitis; (3) Nova Scotia, New England, and Toronto sanatoria patients subjected to multiple chest fluoroscopies; and (4) Swedish women treated with radiotherapy for nonmalignant breast conditions. In each of these series, there was a higher than expected number of women who developed breast cancer. The cancer developed at an earlier age than in nonirradiated women. In cases in which only one breast was irradiated, there was a correspondence between the irradiated side and subsequent development of breast cancer. The breast cancer incidence rate showed a striking dependence on age of the patient at first irradiation. Generally, women irradiated at ≤ 30 yr of age had a significantly increased risk of breast cancer. In the Group 2 women, however, irradiation postpartum after age 30 did not confer an absolute breast cancer risk substantially different from that seen in women irradiated prior to age 30. It is suggested that full-term pregnancy returns the breast to an earlier, more sensitive physiologic state. (40 refs)

79-1245 Radiation and the Induction of Malignancy. (Eng) Hazel, J. J. (Dept. Therapeutic Radiology, Royal Victoria Hosp., Montreal, Quebec H3A 1A1, Canada). *Clin Nucl Med* 4(2): 84-85; 1979.

Information concerning radiation-induced (R-I) malignancies is reviewed briefly. The topics covered include the pathogenesis of R-I tumors, pathogenesis, body areas susceptible to R-I carcinogenesis, significance of radiation dose, and the prognosis of R-I malignancies. (14 refs)

79-1246 The Role of X-Ray Pelvimetry in Modern Obstetrics. (Eng) Granados, J. L. (No affiliation given); Haskins, A. L.; Lahom, L. R. *Bull Univ Md Sch Med* 63(4): 4-8; 1978.

The hazards to the fetus of low-level radiation, the advantages and limitations of pelvimetry during pregnancy, and the correlation of x-ray pelvimetry to obstetrical outcome are reviewed. The literature suggests that leukemia and possibly other neoplasms and other major causes of death in childhood may be induced by in utero exposure to low-level radiation. (16 refs)

79-1247 Micronesia: America's "Strategic" Trust. (Eng) Johnson, G. (No affiliation given). *Bull At Sci* 35(2): 10-15; 1979.

The medical and sociological consequences of US nuclear bomb testing in the Marshall Islands in the 1940's and 1950's are discussed. Since 1964, > 90% of the children on one atoll, Rongelap, who were < 12 yr old at the time of an explosion in 1954 have developed thyroid tumors. A total of 40% of all exposed Rongelapese have developed thyroid problems. Although the Atomic Energy Commission told inhabitants of a neighboring island, Utirik, that the 14 rads of radiation they had experienced was harmless, 11 thyroid tumors were observed among 157 islanders over 23 yr; in addition, there was a sharp increase in the thyroid disease and cancer rate among the Utirikese in 1977. (13 refs)

79-1248 Genetic Aspects of Carcinogenesis and Carcinogen Testing. (Eng) O'Brien, S. J. (Immunology Section, Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Rice, M. C. *J Toxicol Environ Health* 5(1): 69-81; 1979.

Studies of mammalian cellular genes as targets of carcinogens are reviewed, and the question of inbred vs outbred mice as a model system for human carcinogenesis is considered. More than 30 genes that participate in the generation of leukemias, sarcomas, and carcinomas have been studied in human, mouse, and cat systems in vivo and in vitro. Seventeen of these genes have been localized to a specific chromosome in the particular species, and the rest are being mapped. Three classes of genes have been studied as they are related to tumorigenesis: (1) those controlling the expression of in vitro tissue culture correlates to malignant transformation; (2) those involved in the enzymatic activation of carcinogens; and (3) those related to the replication and expression of endogenous C- and B-type RNA tumor viruses or retroviruses.

Cellular genes that regulate the expression of these viruses are likely chromosomal targets of carcinogens. Three laboratory populations of outbred Swiss-Webster mice were tested for a number of gene-enzyme systems that would electrophoretically resolve the nature and extent of genetic variation. The frequency of polymorphic loci was slightly less than that in wild mice or in humans, but the av heterozygosity was indistinguishable from published estimates for mouse and human. It is concluded that Swiss mice are genetically as well as functionally outbred. (59 refs)

- 79-1249 Structure, Replication, and Recombination of Retrovirus Genomes: Some Unifying Hypotheses.** (Eng) Coffin, J. M. (Dept. Molecular Biology and Microbiology, Tufts Univ. Sch. Medicine, 136 Harrison Ave., Boston, MA, 02111). *J Gen Virol* 42(1): 1-26; 1979.

Structural features of the retrovirus genome and mechanisms for its replication and recombination are reviewed. Retroviruses use a system different from that used by all other known virus groups to ensure that all portions of the genome are copied into double-stranded DNA. The system combines direct terminal repeats in the genome and the ability of the polymerase to move, along with the nascent chain, from one template to another. The mechanisms that relate one proviral DNA structure with another are not yet fully understood. The absence of specific integration sites and the presence of additional information at each end of the integrated provirus suggest that control sequences for initiation and, possibly, termination of virus RNA synthesis are encoded in the virus genome. A model for recombination by breakage repair is proposed. The key assumption is that when a polymerase molecule encounters a break in the template, it behaves the same way as it does when it reaches the end of an RNA template. Thus, the polymerase halts and the template is subsequently degraded by RNase H. This frees the nascent chain for base-pairing, but this time with the corresponding sequence on the other molecule in the dimer. If another break is encountered in the course of subsequent synthesis, the growing chain will be transferred back to the first template and so forth, leading finally to a recombinant virus. (122 refs)

- 79-1250 Type-C Oncornaviruses and Autoimmunity.** (Eng) August, J. T. (Dept. Pharmacology, Johns Hopkins Univ. Sch. Medicine, Baltimore, MD, 21205); Strand, M. *Arthritis Rheum* 20(6, Suppl): S64-S73; 1978.

The participation of an endogenous viral gene in the autoimmune disease of New Zealand Black (NZB) mice is discussed. The viral component most strongly implicated is the 70,000-dalton envelope glycoprotein of an endogenous murine C-type oncornavirus. This glycoprotein is expressed in the cells of all mice independently of the synthesis of virions or other viral proteins. It is found on cell membranes as a viral cell-surface antigen and is also found in serum. In NZB mice, the concentration of glycoprotein in cells and serum is higher than that in other strains, and in some reticuloendo-

thelial and epithelial cells it is a major cell protein constituent. Evidence indicates that the mice are not immunologically tolerant to the glycoprotein and that immune complex deposition occurs in the kidneys of both NZB mice and aging mice of other strains. Several genes appear to be involved in NZB autoimmune disease, and the presence of high concentrations of virus gene product alone is insufficient to induce it. There is no clear evidence as to whether or not the endogenous virus is a necessary factor or one of several factors that can influence the disease process in an appropriate host. (63 refs)

- 79-1251 Biosynthesis of Murine Leukemia Virus Membrane Proteins and Their Assembly into Virus Particles.** (Eng) Arlinghaus, R. B. (Biology Dept., Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Murphy, E. C.; Naso, R. B.; Arcement, L. J.; Karshin, W. L. *ACS Symp Ser* 80: 180-200; 1978.

Events leading to the formation of mature viral envelope proteins and their assembly into virions are summarized. In addition, a model for virion assembly and budding of the virus particle from the cell is proposed. Topics discussed include the virion proteins of Rauscher murine leukemia virus (R-MuLV), intracellular viral specific glycoproteins, presence of gp69/71 and p15(E) peptide sequences in gPr90-env, the gene order of the proteins within gPr90-env, viral protein p12(E), cell-free synthesis of an unglycosylated precursor to gp69/71 and p15(E), peptide maps of the envelope-related protein synthesized from intracellular 20S-22S messenger RNA, and translation of fractionated R-MuLV genomic RNA. These studies and those of others indicate that there are at least two size classes of messenger RNA's that code for R-MuLV proteins. A smaller size class of messenger RNA (approx 22S) apparently codes for the envelope proteins. A model for the synthesis and processing of R-MuLV proteins is described. According to the virus-assembly model, cleavages of Pr65-gag and Pr200-gag-pol are probably required for virus budding and release. However, it is possible that Pr65-gag and Pr200-gag-pol may be cleaved not during budding but after release of virus from the cell. (62 refs)

- 79-1252 Fucosylation--A Role in Cell Function.** (Eng) Glick, M. C. (Dept. Pediatrics, Univ. Pennsylvania Medical Sch., Children's Hosp. Philadelphia, Philadelphia, PA, 19104). *ACS Symposium Series* 80: 404-411; 1978.

The fucose (FC)-containing glycopeptides of the membranes of virus-transformed and tumor cells are different from those of normal cells: the glycopeptides are more highly branched on the virus-transformed cells. Although FC served as a radioactive marker to detect these differences, no difference has been found in FC per se. The similarities of FC among several cell types and some unique properties of FC in mammalian glycoproteins are summarized and used to suggest that FC may play a special role in the relationship of the surface mem-

brane to the cell. Three observations are directly suggestive of a role for FC: (1) most membrane glycoproteins are fucosylated; (2) FC is positioned near the glycopeptide core; and (3) α -L-fucosidase activity is not significantly elevated after virus transformation. Furthermore, FC is the only monosaccharide that occurs as an L-isomer and a deoxy sugar but never as the N-acetyl derivative, which suggests that FC may be in a unique position because of its structure alone. Relatively large amounts of two unusual components are associated with the surface membrane containing FC. One is the major high-mol-wt glycoprotein excreted by human fibroblasts in culture, and the other is a low-mol-wt component of the cell surface. Finally, FC found in the membrane glycoproteins shows two different rates of acid hydrolysis and two different specific activities. The use of cell-surface variants defective in membrane glycoproteins may be useful in ascertaining the special role that FC may have in the relationship of the surface membrane to the cell. (21 refs)

- 79-1253 The Stabilization of Cell Lines by Viruses.** (Eng) Harnden, D. G. (Dept. Cancer Studies, Univ. Birmingham Medical Sch., Birmingham, England 11). *Prog Clin Biol Res* 26: 11-23; 1978.

The stabilization of cell lines by viruses is discussed. Only a limited number of viruses can alter cells in such a way that they develop into established lines. Among the RNA viruses, only the oncogenic members of the retrovirus group with a C-type morphology can bring about cellular transformation, whereas oncogenic members of all main groups of DNA viruses can do so. A cell infected by an RNA virus may be both transformed and virus-producing, whereas DNA viruses will cause only lytic infections in some cell types and only transformation in others. The transformed cell lines will have unique combinations of the characteristics typical of the transformed phenotype, even when they are induced by the same virus. Viral transformation appears to be necessary but not sufficient for creation of a population of malignant cells or malignant tumor development in vivo. The possibility of generating cell lines altered by a virus but not having a classical transformed phenotype should not be overlooked. (19 refs)

- 79-1254 Herpes Simplex Virus Infections.** (Eng) Felman, Y. M. (Bureau Venereal Disease Control, City New York Dept. Health, New York, NY); Sonnabend, J. A. *NY State J Med* 79(2): 179-185; 1979.

The association of herpes simplex virus (HSV) with cervical cancer (CC) is discussed in this review of HSV infections. Cervical dysplasia, carcinoma in situ, and invasive cervical carcinoma are associated with HSV type 2. However, just as women with genital herpes, associated with HSV type 1 or type 2, may not develop CC, CC can occur in women with no evidence of HSV. Herpesviruses have been shown to transform cells in vitro and to have oncogenic effects in experimental animals. (52 refs)

- 79-1255 Etiology of Lymphomas and Leukemias: Role of C-Type RNA Viruses.** (Eng) Kaplan, H. S. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305). *Leuk Res* 2(4): 253-271; 1978.

The role of C-type RNA viruses in the induction of lymphomas and leukemias is reviewed. Leukemogenic viruses have been isolated from lymphomas and lymphatic leukemias of murine, feline, bovine, Syrian hamster, and subhuman primate origin. Purified RNA tumor virus particles contain RNA-dependent DNA polymerase, reverse transcriptase (RT), which can synthesize complementary DNA from viral RNA templates. The RT's extracted from RNA tumor viruses of different mammalian species can be distinguished immunologically. The viral genome contains four genes, but sequences specifically associated with leukemogenic activity have not yet been identified. The feline, bovine, and gibbon ape leukemia viruses have all proved to be exogenous, horizontally transmitted C-type RNA viruses. The leukemogenic viruses are remarkably selective with respect to the types of target cells they transform. Three classes of antigens have been identified: virion, cell-surface, and soluble antigens. Acute myeloid leukemias were the first reported human source of C-type RNA viral isolates. At least 8/15 cell lines, representing 3 different types of malignant lymphomas, have spontaneously initiated the sustained production of C-type RNA viruses. Normal human peripheral blood and bone marrow cells infected with one of these viruses (DHL-1) have shown changes in their growth behavior and morphology, but these responses have not been sustained. Immunological studies suggest that the RT of DHL-1 virus is unrelated to that of the murine and feline C-type viruses, but is remotely related to the enzyme of subhuman viruses. (296 refs)

- 79-1256 Viral Infections of the Vulva.** (Eng) Josey, W. E. (Emory Univ. Sch. Medicine, Atlanta, GA). *Clin Obstet Gynecol* 21(4): 1053-1059; 1978.

Vulvar infection with herpes simplex viruses types 1 and 2 (HSV-1 and HSV-2) is reviewed. Although a causal role for herpes viruses in human cancers has not been proved, the ability of human herpes viruses to cause neoplastic transformation in tissue culture or in experimental animals has been demonstrated conclusively. HSV-1 infections are chiefly acquired in childhood, and HSV-2 infections occur mainly in adults. HSV-1 is associated primarily with nongenital herpetic infections, HSV-2 with genital herpetic disease. However, 10% of genital infections are caused by HSV-1. In the genitals, HSV-2 infection commonly involves the cervix as well as the vulva, whereas HSV-1 infection is more likely to be confined to the external genitalia and tends to be more superficial than type 2 lesions. Although considerable seroepidemiologic and experimental evidence supports the theory that HSV-2 infection may be etiologically related to carcinoma of the cervix, present information on a possible relation to cancer of the vulva is scanty. There is an association of some vulvar carcinomas with carcinoma of the cervix, suggesting

that the same etiologic factors may be operative in both cancers. There have been reports of cases of marked intraepithelial vulvar atypia approaching carcinoma in situ, occurring as a sequel to HSV-2 vulvitis during pregnancy, that have reverted to normal in the postpartum state. These cases suggest a possible carcinogenic effect of HSV-2 on the vulva under appropriate conditions of host susceptibility. (8 refs)

79-1257 Cutaneous Manifestations Occurring Systemically in Heritable Forms of Colon Cancer. (Eng)

Kopelovich, L. (Memorial Sloan-Kettering Cancer Center, Cornell Univ. Graduate Sch. Medical Sciences, New York, NY, 10021). *Monogr Hum Genet* 10: 156-164; 1978.

Skin fibroblasts from patients with adenomatosis of the colon and rectum (ACR) are defective in growth control and cytoplasmic organization and are differentially transformed by an RNA oncogenic virus. These phenotypic disorders are likely to be systemic and may be related to the presence of early and previously undetected biochemical lesions in skin fibroblasts from ACR genotypes. (49 refs)

79-1258 Immunological Surveillance Against Neoplasia: An Immunological Quandary. (Eng) Drew, S. I.

(Dept. Medicine, Univ. California Sch. Medicine, Los Angeles, CA, 90024). *Hum Pathol* 10(1): 5-14; 1979.

Arguments for and against the theory of immunological surveillance (IS) against neoplasia are reviewed. The IS hypothesis proposes that there is an immunological system capable of recognizing tumor cells as "nonself" and aborting the growth of aberrant cells in the early stage of tumor development. Evidence of tumor induction in immunosuppressed animals challenged with carcinogens and the demonstration of an immune response to tumors in animals support the hypothesis. The concept has also found support in the clinical situation, in which tumor incidence in immunosuppressed individuals is notably increased. The occurrence of tumor, regarded as a failure of IS, is attributed to selection of neoplastic cells for immunological or other reasons or abnormal humoral or cellular antitumor immune responses. However, the monoclonality of certain tumors (multiple myeloma, chronic lymphatic leukemia, Waldenstrom's macroglobulinemia, chronic lymphosarcoma-leukemia, and Burkitt's lymphoma) and the low incidence of spontaneous tumors in genetically immunodeficient mice and immunologically privileged sites argue against the IS hypothesis. On the basis of current evidence, the relationship between spontaneously arising tumors and the immune system may be envisaged as follows: (1) the existence of an IS system as an entity independent of the normal antitumor immune response is a redundant concept; (2) spontaneous neoplastic transformation is a rare in vivo event; (3) therefore, in view of 1 and 2, there is no need for IS; and (4) tumors elicit an immune response, which in most cases fails to intercept tumor growth. (63 refs)

79-1259 The Pathogenesis of Hodgkin's Disease. (Eng) Stuart, A. E. (Dept. Pathology, Univ. Newcastle upon Tyne, Tyne NE1 4LP, England). *J Pathol* 126(4): 239-254; 1978.

The histopathology of Hodgkin's disease (HD) is reviewed in relation to experimental findings. Serum immunoglobulins are increased in many patients with untreated HD, and serum factors that depress in vitro lymphocyte responses to mitogens, modify erythrocyte (E)-rosette-forming ability, or bind to T lymphocytes have been described. Lymphocytopenia often occurs in HD, and atypical lymphocytes have been repeatedly described, as has increased spontaneous DNA synthesis by blood T lymphocytes. The absolute number of T lymphocytes is often slightly reduced, and B cells may be raised in number. There seems to be a specific interaction between serum factors and the surface of peripheral T lymphocytes, and there is a distinct redistribution of T cells between blood, spleen, and lymph nodes. The Reed-Sternberg cells identified in patients with HD appear to be neoplastic, and it is likely that they are derived from a disordered B cell that matures through a sequence of mononuclear and polynuclear forms. The tendency for T lymphocytes to swarm around viable Reed-Sternberg cells appears to be an integral part of the HD process and may be significant in the evolution of the disease. The ecotaxis of T cells in HD is probably a reflection of this interaction between T lymphocytes and Reed-Sternberg cells. (99 refs)

79-1260 Membrane Biochemistry and Physiology of Human Colonic Cancer. (Eng) Freeman, H. J. (Veterans Admin. Hosp., San Francisco, CA); Kim, Y. S. *Cancer Bull* 30(6): 237-242; 1978.

Studies concerning the normal cell membrane and alterations in glycoproteins, glycolipids, cell-surface tumor antigens, and transport in colonic cancer are reviewed. Features that differentiate malignant from normal cells include the ability to grow and proliferate independently of normal control mechanisms, to invade normal tissues, and to metastasize to distant sites. Increasing evidence indicates that these characteristics are largely controlled or modulated by the tumor cell nucleus and surface membrane. Significant membrane alterations occur in colonic malignancy, and they include changes in certain blood group activities of membrane glycoproteins and glycolipids and expression of cell-surface membrane tumor antigens. Elucidation of the precise molecular basis for these cell-surface membrane alterations may lead to improved detection and treatment of colonic cancer. In addition to specific malignant alterations of membrane components, functional changes associated with malignant transformation include changes in membrane transport of certain nutrients. Increased transport of glucose, several glucose analogs, mannose, galactose, glucosamine, and various amino acids occurs with transformation. In general, V_{max} increases but K_m remains unchanged or is decreased. This suggests that the number of transport sites in carrier-mediated uptake is increased for various nutrients. Changes in membrane proteins in rela-

tion to the membrane uptake and transport of certain chemotherapeutic agents also appear to occur with neoplasia. (26 refs)

- 79-1261 Genitourinary Tumors and Immunology.** (Eng) Lange, P. H. (Minneapolis Veterans Admin. Hosp., Minneapolis, MN). *Proc Inst Med Chic* 32(4): 58-59; 1978.

Progress in the field of genitourinary tumor immunology is reviewed. Studies of immunotherapy have been carried out in patients with renal cell carcinoma, transitional cell carcinoma, and prostatic cancer, and the immunotherapeutic agents studied have included BCG, transfer factor, immune RNA, and serum cross transfusion. Several serological tumor markers have proved useful in the management of patients with testicular tumors. Another area of human tumor immunology is the detection and characterization of antigens on the tumor cell per se. (4 refs)

- 79-1262 Experimental Tumors of the Urinary System.** (Bul) Stoichev, I. (Lab. Chemical Carcinogenesis, Res. Inst. Oncology, Sofia, Bulgaria). *Onkologiya* 15(3): 148-155; 1978.

Data on chemically induced tumors of the urinary system are reviewed. Chemicals that induce urinary system tumors include aromatic amines, nitrosamines, nitrofurans, chemical compounds of natural origin (some antibiotics, aflatoxin, methylazoxymethanol acetate), and various metabolites. Histologically, the induced tumors are papillomas, adenomas, and carcinomas. (64 refs)

- 79-1263 Report of the Workshop on Mutagenicity.** (Eng) Roderick, T. H. (Jackson Lab., Bar Harbor, ME). *J Toxicol Environ Health* 5(1): 163-165; 1979.

Mammalian systems that are used to test transmissible mutagenic damage or that have direct relevance to transmissible effects were discussed at a mutagenicity workshop, and the findings are reviewed. The dominant lethal, translocation, specific locus, X-chromosome loss, unscheduled DNA synthesis, and sperm abnormality tests are described briefly. (no refs)

- 79-1264 Genetic Structure of Human Populations.** (Eng) Schull, W. J. (Center Demographic and Population Genetics, P.O. Box 20334, Houston, TX, 77025). *J Toxicol Environ Health* 5(1): 17-25; 1979.

The difficulties of extrapolating the toxicity responses of experimental organisms to humans are discussed. Contemporary methods of evaluation assume little heterogeneity among members of the human population in their response to a substance. However, measurement of enzymic variation reveals

that humans are more variable genetically than most mammalian species. In one study in which 10 mammalian species were examined, human heterozygosity values were two to six times greater than those of 2 primates (both macaques) and more than twice as great as those of most feral rodents represented. Evaluation of toxicological hazards should also consider responses to potentially toxic substances by individuals who carry rare genetic alleles. The effects of population structure (its system of mating and its effective size, as well as its patterns of reproduction, mortality, and migration) on genetic variability are also discussed. In contemporary human populations, migration rates are not sufficiently restricted and inbreeding and phenotypic assortative mating rates are not sufficiently large to play important roles in limiting genetic diversity. Hidden genetic variability in humans could be enormous, leading to much wider responsiveness to the toxic effects of environmental chemicals than presently appreciated. Seemingly harmless drugs or food additives (as judged from animals less diverse than humans) may, in fact, have serious toxic effects on a nontrivial number of humans because of the great genetic diversity present. (32 refs)

- 79-1265 Cancer Metastasis: A Product of Tumor-Host Interactions.** (Eng) Sugarbaker, E. V. (Dept. Surgery and Oncology, Univ. Miami, Miami, FL). In: *Curr Probl Cancer* 3(7): 1-59; 1979.

Clinical and experimental data on metastasis are reviewed extensively. A number of studies have demonstrated the systemic dissemination of cancer cells early in the course of certain malignancies. Cancer cells must complete three phases, entrance into a vascular conduit, transportation to a distant organ or lymph node, and lodging and growth at the distant site, before they can become metastases. Cell characteristics favoring metastasis are listed. In addition, the site and size as well as genetic characteristics of the primary tumor modulate metastasis. Despite the growing body of data demonstrating the presence of immunostimulation of certain phases of neoplastic growth and metastasis, other data implicate immune rejection in metastasis. Extensive macrophage infiltration into primary tumors has also suggested a modulating role of macrophages in metastasis. Large numbers of tumor cells are probably also destroyed by nonimmunologic and nonspecific means. Heterogeneity has recently been definitively demonstrated in tumor cell populations, indicating that the metastatic cell may be analogous to clonal selection of mutant subpopulations derived from a common progenitor for neoplastic progression. The stage of a malignant disease (size of primary, presence or absence of histologically identified positive regional nodes) is the dominant determinant in patient prognosis. (191 refs)

- 79-1266 Induced Chromosome Variation in Cultured Cell Populations.** (Eng) De Carli, L. (Istituto di Biologia, Facolta di Medicina, Universita, Milano, Italy 93); Larizza, L. *Prog Clin Biol Res* 26: 93-124; 1978.

Spontaneous and induced variations in chromosome number and structure in cultured cell populations are reviewed. Chromosome variability has been used as an alternative to genetic variation via sexual reproduction for genetic analyses and has been employed in gene localization studies and in studies of the dynamics of karyotypes in neoplastic cells. Chromosome changes occur spontaneously in culture as a result of duplication or distribution errors. They can be induced in mammalian cultured cells by a variety of physical and chemical agents, including classical mutagens (ie, ionizing radiation, chemical compounds), changes in temperature or ionic strength, c-mitotic agents, and the antifungal agent griseofulvin (GF). The pattern of chromosome variation induced by these agents resembles that observed during the transition from primary culture to permanent in vitro line, and it has been suggested that GF-induced chromosome variations might facilitate the establishment of a cell line in vitro. One of the most effective ways of activating the dynamics of chromosome complements in vitro is the somatic cross, which brings about the formation of combined chromosome sets. The cytogenic structure of a cell population can also be manipulated by treatment of cells with morphologically intact metaphase chromosomes. The partial hybridization resulting from the incorporation of mitotic chromosomes suggests that chromosome transplantation may be a new method for gene localization. It would not be subject to the restrictions imposed by the directional loss of chromosomes in interspecific hybrids. (62 refs)

- 79-1267 Ectopic Insulin and Occam's Razor: Reappraisal of the Riddle of Tumour Hypoglycaemia.** (Eng) Skrabanek, P. (Endocrine Unit, Mater Misericordiae Hosp., Dublin, Ireland); Powell, D. *Clin Endocrinol (Oxf)* 9(2): 141-154; 1978.

The concept of ectopic insulin (IL) production is challenged on the basis of a review of 120 literature cases on extrapancreatic tumors associated with hypoglycemia in which IL or IL-like activity was measured. None of the cases given in support of the concept of ectopic IL met two or more of the following five criteria of ectopic hormone production: (1) greater concentration of IL in tumor than in surrounding normal tissue; (2) immunohistochemical localization of IL in tumor; (3) normalization of IL and of blood glucose concentrations after tumor removal; (4) arteriovenous gradient of IL concentration across the tumor bed; and (5) IL production by tumor in vitro. Several of these cases had a carcinoid histology. A close association was also observed between some spindle-cell tumors and carcinoid tumors. It is stressed that hypoglycemia is quite common as a terminal manifestation of malignancy because of a variety of causes; ie, cachexia, malabsorption, and impaired liver function. Nonsuppressible IL-like activity (NSILA), consisting of a number of factors mimicking IL activity that compete with IL or pro-IL for membrane receptors and may cross-react in various assays, was detected in 5/7 patients with hypoglycemic tumors by one investigator but not confirmed by another. It is possible

that one or several of these substances may be responsible for extrapancreatic hypoglycemia. (123 refs)

- 79-1268 Radiological Techniques in the Examination of Patients with Headaches.** (Eng) Komar, N. N. (1601 N. Tucson Blvd., Bldg. 1, Tucson, AZ, 85716). *Med Clin North Am* 62(3): 585-620; 1978.

In the radiologic investigation of headache patients, the principal recommended procedures are plain film study (PF) of the skull, computed tomography (CT), echoencephalography, and radionuclide brain scanning, particularly the first two. Special procedures such as cerebral angiography, pneumoencephalography, and posterior fossa myelography are usually performed when one of the noninvasive studies indicates a structural lesion or when the patient has a complex clinical presentation. PF evidence and localization of a tumor may be found when the cranial vault is involved, such as with meningioma. Almost any tumor that metastasizes to bone may do so to the cranial vault. Erosion of the sella turcica is found in one-third of patients with brain tumor. Approx 15% of all intracranial neoplasms are meningiomas. The cardinal PF signs of this tumor are hyperostosis, increased calvarial vascularity, and tumor calcification. PF evidence of calcification can also be found in approx 10% of glioma patients. CT is accurate and cost-efficient in the work-up of an individual suspected of harboring a brain tumor. At clinical presentation, many intracranial lesions have produced a definite mass. Most tumors are of low tissue density, but a gradation of low through normal to high density has been demonstrated by CT. The mass may be solid or cystic, it may be surrounded by edema, and it may contain inherent neovascularity. Enhancement by iv contrast material has been shown in 60% of supra- and infratentorial tumors and, when present, is an accurate determination of the boundary between tumor and surrounding edema. Low-grade astrocytomas tend to cause little mass effect or tissue reaction and thus are difficult to detect. Lesions such as cerebellar astrocytoma, metastasis, ependymoma, medulloblastoma, hemangioblastoma, and meningioma may all show CT evidence of the mass and edema effect, and a significant number will show contrast enhancement. (30 refs)

- 79-1269 Headaches and Head Pains Associated with Diseases of the Ear, Nose, and Throat.** (Eng) Birt, D. (Dept. Otolaryngology, Sunnybrook Medical Center, 2075 Bayview Ave., Toronto, Ontario M4N 3M5, Canada). *Med Clin North Am* 62(3): 523-531; 1978.

The identification or elimination of malignant disease is the crux of many otolaryngology consultations. Pain is a common symptom of malignant disease. Among the sinuses, the antrum and ethmoid are the most common sites for neoplastic disease. Sinus cancer often presents late, as signs and symptoms may not occur until the neoplasm has escaped the sinus itself. A wide spectrum of neoplasms may involve the sphenoid sinus, including squamous carcinoma, adenoidcys-

tic carcinoma, lymphoma, chondroma, chondrosarcoma, craniopharyngioma, meningioma, pituitary tumor, and angiofibroma. These tumors may cause bone erosion and pressure on surrounding structures, with visual disturbance, proptosis, and ophthalmoplegia also common. Malignant disease of the ear is rare, but should be considered if pain begins in a chronic discharging ear. Nasopharyngeal carcinoma NPC shares with the sphenoid the ability to cause headache in various places and also pain deep to the ear. Other presenting features of NPC include enlarged upper cervical lymph nodes, unilateral serous otitis, and nasal symptoms, and any combination of nerve palsies. Although NPC is most common in the fifth decade of life, it occurs frequently in young adults, particularly those of Southern Chinese origin. It also occurs in children. Pain arising from malignant disease in the oropharynx, hypopharynx, and supraglottic larynx is usually described as a sore throat or pain in the throat on swallowing, and there may be some earache. Glottic laryngeal carcinoma is seldom painful in the absence of perichondritis. (4 refs)

- 79-1270 Pathology of the Ear: Selected Topics.** (Eng) Friedmann, I. (No affiliation given.). *Pathol Annu* 13(1): 363-410; 1978.

Inflammatory diseases and neoplasms of the ear are reviewed. Inflammatory diseases considered include epidermoid cholesteatoma, cholesterol granuloma, catarrhal or secretory otitis media, and tympanosclerosis. Nonhealing (malignant) external otitis occurs in elderly diabetic patients and is caused by *Pseudomonas pyocyanea*. Neoplasms of the ear are rare, with an estimated incidence of 0.006/1,000 persons. The most common malignant neoplasm of the ear is squamous cell carcinoma. The pinna is the site of both squamous and basal cell carcinoma; distant metastases from squamous carcinomas of the ear are uncommon. Malignant glandular neoplasms of the ear are mainly of ceruminous gland origin. The predominant morphologic types of ceruminoma have been classified as follows: ceruminous adenoma, ceruminous adenocarcinoma, pleomorphic adenoma (mixed tumor), and adenoid-cystic carcinoma or cribriform adenocarcinoma. Schwannoma of the auditory nerve accounts for about 8% of all intracranial tumors. It is seen most often in the third and fourth decades of life and frequently presents as a cerebellopontine angle tumor. Cerebral neoplasms that may affect the ear include meningiomas, gliomas, and glioblastomas. In addition to rhabdomyosarcoma, which is the most common sarcoma of the ear, fibrosarcoma, osteosarcoma, and chondrosarcoma may also occur. Paragangliomas, which arise from the jugular bulb or from the promontory, are difficult to diagnose as malignant or benign on a histological basis. There is little information about the frequency of metastases in the temporal bone. (186 refs)

- 79-1271 Odontogenic and "Fissural" Cysts of the Jaws.** (Eng) Gardner, D. G. (No affiliation given.); Sapp, J. P.; Wysocki, G. P. *Pathol Annu* 13(1): 177-200; 1978.

The incidence, location, differential diagnosis, and histology of odontogenic and fissural cysts of the jaws are reviewed. The odontogenic keratocyst is important because of its aggressive behavior, its marked tendency to recur after surgical removal, and its association with the basal cell nevus syndrome. Additional features of this syndrome are multiple basal cell carcinomas, often occurring at an early age, skeletal anomalies, and a lack of response to parathormone. The possibility of this syndrome should be considered in any patient in whom an odontogenic keratocyst is diagnosed. The most common cyst of the jaws, the radicular cyst, is of inflammatory origin and develops within a periapical granuloma. It is lined by stratified squamous epithelium that often exhibits marked proliferation into the underlying connective tissue, a feature that has occasionally led to consideration of the diagnosis of ameloblastoma. However, ameloblastomas do not develop in radicular cysts. Squamous cell carcinoma has been reported on rare occasions in these cysts. Ameloblastomas may develop in dentigerous cysts, a common odontogenic cyst that occurs around the crown of an unerupted tooth. Mucoepidermoid carcinomas have also been observed on rare occasions in continuity with the epithelial lining of odontogenic cysts. Fissural cysts are developmental cysts of the jaws that are not derived from odontogenic epithelium, and they include nasopalatine duct, globulomaxillary, nasolabial, and median palatal cysts. (31 refs)

- 79-1272 Bras, Breast Carcinoma, and Cryptorchid Testis (Letter to Editor).** (Eng) King, C. R. (Dept. Obstetrics and Gynecology, Kansas Univ. Medical Center, Kansas City, KS, 66103). *Lancet* 1(8106): 45; 1979.

A previous suggestion that breast temperature is implicated in the etiology of breast neoplasia is criticized. It is difficult, without measuring the temperature within the breast tissue itself, to propose that glandular breast tissue has been exposed to unnatural temperatures by the dictates of fashion. A second previous suggestion that the high cancer incidence in undescended testes is caused by glandular tissue overheating is also criticized. Evidence that a testis is cryptorchid because it is abnormal is summarized. (10 refs)

- 79-1273 Pathology of Early Squamous Cell Carcinoma of the Lung.** (Eng) Carter, D. (No affiliation given). *Pathol Annu* 13(1): 131-147; 1978.

The detection, localization, and morphology of the early stage of squamous cell carcinoma of the lung, ie, the time before the patient becomes symptomatic and before the lesion is evident on plain chest x-ray, are reviewed. These lesions can only be detected by cytologic examination of the sputum. The chest x-ray of patients with positive sputum should be reviewed for suspicious areas that might have been overlooked. If this is not the case, the only means of localization of a bronchial lesion is a meticulous study of the upper airway and then the tracheobronchial tree, using a flexible fiberoptic bronchoscope. In 20 patients with preclinical squa-

mous cell carcinoma, in situ carcinoma was present in all cases but invasive carcinoma was present in only 12. The distribution of invasive carcinoma suggests that these lesions usually arise in segmental bronchi. The in situ carcinoma begins in the surface epithelium, usually in a segmental bronchus, from which it may spread in several directions. It frequently spreads in a proximal direction to involve lobar bronchi. It may also spread from the surface to involve the submucosal glands, and it may extend deep to the bronchial cartilage rings prior to the time that invasion occurs. The proximity of the invasive cancer to the bronchial cartilage makes its detection on x-ray difficult. Four of the 20 patients showed evidence of multifocal disease, a rate that had been suggested by other studies. (25 refs)

- 79-1274 The Mechanism of Bronchial Carcinogenesis.** (Fre) Masse, R. (Laboratoire de toxicologie experimentale, Departement de protection, Commissariat a l'energie atomique, Institut de protection et de surete nucleaire, BP 561, 92542 Montrouge Cedex, France); Arnoux, B. *Rev Prat* 28(59): 4679-4685; 1978.

Most human bronchial cancers are induced by chemical carcinogens, and tobacco smoke inhalation is the dominant etiological factor. The first stage of carcinogenesis is cellular and leads to the genetic transformation of a line. This stage depends on the target cell's sensitivity and on an individual's predisposition to cancer. A tissular stage contributes to clonal regulation and local accumulation of carcinogens. Expression of the initial lesion depends on the host immune system. The various stages are strongly influenced by cofactors. (10 refs)

- 79-1275 Spectrum of Lung Cancer and Ectopic Hormones.** (Eng) Yesner, R. (No affiliation given). *Pathol Annu* 13(1): 217-240; 1978.

Studies of production of ectopic hormones in patients with lung cancer are reviewed. Clinical syndromes associated with ectopic hormone production occur in 10% of all patients with lung cancer. Small cell carcinomas, particularly the oat cell type, produce the most ACTH, but it is also produced in significant amounts by all other types. Two forms of ACTH have been identified: "little ACTH" (39-amino acid polypeptide), which is the predominant form in normal pituitary extracts, and "big ACTH," which is the major component in lung tumors. Small cell carcinomas also produce more antidiuretic hormone (ADH) and calcitonin than the other types. Parathyroid hormone is almost exclusively produced by squamous cell carcinoma. Human growth hormone (HGH) is chiefly produced by adenocarcinomas and large cell carcinomas. Because there is an association of hypertrophic pulmonary osteoarthropathy (HPOA) with acromegaly, there has been much interest in the observation that tumors causing HPOA may also secrete HGH. HPOA is associated predominantly with adenocarcinomas, to a lesser extent with squamous cell carcinomas, and not at all with small cell carcinomas. The glycoproteins are predominantly but not

exclusively associated with large cell carcinomas, some of the giant cell type. These findings suggest that the degree, rather than the kind of hormone secretion, may be associated with the level of tumor maturation. (109 refs)

- 79-1276 General Review: Liver and Oral Contraceptives.** (Fre) Rauber, G. (Nancy, France). *Ann Gastroenterol Hepatol (Paris)* 14(6): 405-414; 1978.

The literature on benign and malignant hepatic tumors attributed to the use of oral contraceptives is reviewed. The pathogenesis of the tumors is discussed. Clinical symptoms may appear slowly or abruptly. Treatment is always surgical, and the postoperative mortality is not negligible. Patients who survive surgery have a good prognosis. (69 refs)

- 79-1277 Balkan Nephropathy.** (Eng) Hall, P. W. (Dept. Medicine, Case Western Reserve Univ., Sch. Medicine, Cleveland Metropolitan Hosp., 3395 Scrawton Rd., Cleveland, OH); Dammin, G. J. *Nephron* 22(4/6): 281-300; 1978.

Literature concerning endemic Balkan nephropathy (BN), a chronic tubulointerstitial nephropathy, is reviewed. There is a high incidence of BN in geographically restricted areas of Bulgaria, Romania, and Yugoslavia. Evidence pointing to environmental rather than genetic factors is substantial. However, the disease often occurs among multiple family members. Predominant tubular abnormalities, including tubular proteinuria, are the earliest manifestations of BN. The tubular proteinuria persists and becomes more prominent with the development of clinically detectable disease. Although the nature of the initial renal lesion remains controversial, a tubulointerstitial lesion accompanied by marked concentric atrophy and fibrosis of the subcapsular cortex is present in patients with azotemia. The inner cortex is less involved than the outer cortex. There is a high frequency of papillary transitional cell carcinoma of the renal pelvis and ureter in the same geographical areas in which BN is prevalent. The data suggest that BN is a definite entity. (70 refs)

- 79-1278 Germ Cell Tumors of the Ovary.** (Eng) Kurman, R. J. (No affiliation given.); Norris, H. J. *Pathol Annu* 13(1): 291-325; 1978.

Specific ovarian germ cell tumors are defined, and their diagnosis, behavior, and therapy are discussed. Benign cystic teratomas, about 1% of which become malignant, are the most common ovarian tumors, accounting for 14%-19% of all neoplasms at this site. Struma ovarii are teratoid tumors in which thyroid tissue represents more than half of the tumor component. A diagnosis of carcinoma has been made in 5% of struma ovarii, but metastasis has been reported in less than half of these; in many cases, the carcinomas in struma ovarii are not truly malignant. Carcinoid and strumal carcinoid tumors are also found in the ovary. Primary carcinoids

have not been known to metastasize; and there has been only one report of malignant behavior of a strumal carcinoid. The most common malignant ovarian germ cell tumor is dysgerminoma, followed by endodermal sinus tumor. However, dysgerminomas are rare, comprising only 2.5% of ovarian tumors. The majority of the patients are 10-30 yr old. Immature (malignant) teratoma is composed of variable amounts of immature tissue derived from any or all of the three germ layers, and it accounts for 1% of teratomas. It is frequently found in children. The malignancy of immature teratoma is related to its clinical stage and histologic immaturity. Endodermal sinus tumor occurs more frequently than pure immature teratoma. The patients range from age 14 mo to 45 yr. The tumor has an extremely rapid growth, with half of the patients presenting with symptoms of 7-day duration or less. Other malignant ovarian germ cell tumors include embryonal carcinoma (5%), choriocarcinoma, and mixed germ cell tumors (8%). (100 refs)

- 79-1279 Cutaneous and Vulvar Melanoma: An Update.** (Eng) Silvers, D. N. (Columbia Univ. Coll. Physicians and Surgeons, New York, NY); Halperin, A. J. *Clin Obstet Gynecol* 21(4): 1117-1133; 1978.

The diagnosis and treatment of cutaneous melanoma (CM) are reviewed with emphasis on vulvar melanoma. Most primary CM's have an in situ or superficially invasive phase of at least several years, during which time the tumor extends in a radial rather than vertical direction. Lentigo malignant melanoma, which accounts for 10% of all CM's, is rarely seen in the perineal region since it develops only on sun-exposed skin. Superficial spreading melanoma, which accounts for 80% of all CM's, can closely mimic a benign melanocytic nevus in its early invasive phase. However, after it has reached a diameter of >1 cm, it has characteristic clinical features, including an irregular, jagged border and a spectrum of colors. Nodular melanoma, which represents 10% of all CM's, does not have a clinically identifiable in situ phase, and by the time it has caused suspicion, it has already invaded to a depth suggestive of a poor prognosis. Follow-up studies of patients with primary CM have demonstrated that tumor thickness at the time of excision is closely correlated with prognosis. Melanoma accounts for 8%-11% of all invasive malignancies of the vulva. In 11 series totaling 352 cases, most lesions arose on the mucous membrane portion, specifically the labia minora and the clitoris. (34 refs)

- 79-1280 Vulvar Dystrophies.** (Eng) Kaufman, R. H. (Baylor Coll. Medicine, Houston, TX); Gardner, H. L. *Clin Obstet Gynecol* 21(4): 1081-1106; 1978.

Studies of vulvar dystrophies and of their significance with regard to malignant potential are reviewed. Most hyperplastic lesions previously called leukoplakia represent examples of lichen simplex chronicus (neurodermatitis). Vulvar dystrophies that exhibit atypical epithelial hyperplasia (dysplasia) are far more significant with regard to malignant potential

than benign epithelial hyperplasias. Most of these lesions are well-localized, delineated, slightly elevated, white, and rough. In lichen sclerosus, the skin has a crinkled parchmentlike appearance. Lichen sclerosus is often associated with both foci of hyperplastic epithelium and atrophic changes. The likelihood that a superimposed vulvar carcinoma will develop in a patient with chronic vulvar dystrophy is small, ranging from 1% to 5% over a long period. The patient who is probably destined to develop cancer is the one with microscopically proved atypical hyperplasia at the initial examination. In the absence of atypia in the dystrophic lesion, the danger of a subsequent carcinoma is almost nil. However, any chronic irritation of the vulva will add to the risk of carcinoma. (40 refs)

- 79-1281 Current Concepts of the Aetiology, Pathogenesis and Pathology of Bladder Cancer.** (Eng) Friedell, G. H. (Dept. Pathology, St. Vincent Hosp., Worcester, MA). *Urol Res* 6(4): 179-182; 1978.

More than one chemical carcinogen or combinations of chemical and biological agents may be involved in the etiology of bladder cancer (BC). In the US, most BC's are transitional cell carcinomas. Regardless of etiology, the pathogenesis of human BC appears comparable to carcinoma of the uterine cervix, bronchus, or oral cavity. Preneoplastic lesions, an experimental model for bladder carcinogenesis, irreversible epithelial hyperplasia, and the cellular characteristics of human BC are discussed. (19 refs)

- 79-1282 Nutritional Considerations in Colon Cancer Kinetics.** (Eng) Stragand, J. J. (Dept. Lab. Medicine, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX). *Cancer Bull* 30(6): 232-236; 1978.

Studies concerning the relationship between nutrition and intestinal cell and colon cancer cell kinetics are reviewed. Several studies have shown that dietary composition can produce distinct growth kinetic changes in the intestine and that the development of a malignant colonic lesion is preceded by a pattern of cell kinetics events that appear in both humans and experimental animals. Other studies have shown that the nutritional status of the host can markedly influence the growth kinetics of spontaneous and transplantable tumors in experimental animals. Studies of the cell kinetics of human colonic lesions have indicated that the overall production of cells is greater in the surrounding normal mucosa than in the tumor itself, which indicates that treating most colonic lesions with cycle-active antiproliferative agents could produce more damage in the coexisting normal tissue than in the targeted tumor cells. This indicates the need for a pretreatment strategy, possibly nutritional manipulation, that would be a nonspecific, tumor-synchronizing agent(s) with little or no normal tissue toxicity. Several theories concerning the etiology of large bowel cancer suggest the involvement of luminal carcinogens. The duration of exposure to these carcinogens

would be proportional to the intestinal turnover time. Because the presence of luminal material has been shown to stimulate cell production, a high-bulk diet might prevent the induction of cancer by reducing exposure to luminal carcinogens. (40 refs)

- 79-1283 Acute Scrotum.** (Ger) Rothenberger, K. (Urologischen Klinik, Städtisches Krankenhaus, Thalkirchner Strasse 48, 8000 Munich 2, W. Germany); Bowering, R. In: *National Cancer Week. Proceedings of the Annual Scientific Meeting held in Adelaide, Australia, 20-24 November 1978.* Clinical Oncological Society of Australia. 175 pp.; p. 170; 1979.

The differential diagnosis of diseases, including testicular tumors, that are manifested as acute scrotum (acute scrotal pain) are reviewed. (no refs)

- 79-1284 Methodology of the Study of Carcinogens in Human Populations.** (Eng) Shabad, L. M. (Dept. Carcinogenic Agents, Cancer Res. Center, Soviet Acad. Medical Sciences, Moscow, USSR). *J Toxicol Environ Health* 4(4): 637-643; 1978.

Primary approaches to study of the effects of chemical carcinogens on human health are epidemiologic and quantitative determinations of the effects of hazardous agents in different environments. Problems in determining max allowable concentrations of chemical carcinogens and extrapolating the findings to humans are also reviewed. (20 refs)

- 79-1285 Hereditary Cancer.** (Eng) Knudson, A. G. (Inst. Cancer Res., Philadelphia, PA). *JAMA* 241(3): 279; 1979.

A concurrently published article concerning a family with hereditary cancer is summarized briefly. Members who inherited the responsible dominant Mendelian gene had a high incidence of sarcomas, brain tumors, leukemias, and breast cancer, a nonrandom segment of the cancer spectrum. Other dominantly heritable neoplasias (ie, retinoblastoma, colon cancer associated with polyposis coli) show similar features. In many cases, the mutant genes have considerable specificity for one tumor or for a select tumor group. The mechanism of predisposition is not known for any of these dominantly inherited disorders. (1 ref)

- 79-1286 Methodologic Problems in Evaluating the Carcinogenic Risk of Environmental Agents.** (Eng) Strassburg, M. A. (County Los Angeles Dept. Health Services, Preventive/Public Health, Acute Communicable Disease Control, 313 N. Figueroa St., Los Angeles, CA, 90012); Greenland, S. *J Environ Health* 41(4): 214-217; 1979.

A paper that purported to prove a link between fluoridation of the water supply and cancer was evaluated to illustrate several pitfalls of data analysis that may occur in scientific papers. In evaluating any study of the relationship between cancer and potential carcinogens, several important points must be addressed: (1) exclusion of data may bias study results and should be carefully justified; (2) claims that a specific agent caused a change in death rates must be examined in terms of the rates both before and after exposure to the agent; and (3) in epidemiological observations, potential confounding variables must be considered. In the paper in question, these criteria were not followed. For example, three nonfluoridated cities were excluded from the study, and these three cities have cancer death rates that are 20%-27% higher than the national av. In addition, the fluoridated cities had the highest cancer death rates both before and after fluoridation was introduced. Industrialization may have been a confounding epidemiological factor, since the fluoridated cities are much more industrialized than the nonfluoridated ones. It is concluded that although the paper claims to have rallied impressive evidence linking cancer and fluoridation, it failed to provide evidence capable of withstanding careful scrutiny. This critique does not argue that fluoridation is safe or that it is not carcinogenic, but rather it presents scientific standards against which investigations should be judged. (6 refs)

- 79-1287 Epidemiology of Hemoblastoses.** (Rus) Gus'kova, A. K. (No affiliation given). *Probl Gematol Pereliv Krovi* 24(2): 58-59; 1979.

Current Soviet literature on the epidemiology and etiology of hemoblastoses is summarized briefly. The fact that certain ethnic factors, as well as sex and age, can affect the frequency of various variants of leukemia is indicative of their important role in leukemogenesis. (no refs)

- 79-1288 Multiple Myeloma: A Cluster in Virginia?** (Eng) Ende, M. (121 S. Market St., Petersburg, VA, 23803). *Va Med* 106(2): 115-116; 1979.

A community cluster of multiple myeloma was investigated. Between 1971 and 1978, 15 cases of multiple myeloma occurred in a small target area of Petersburg, Virginia. The 15 cases were among a total of 21 diagnosed in the entire city of Petersburg. The observed incidence of the disease in the target area far exceeded the expected rate of 1.6-2.4/100,000, the population of the target area being 15,000-17,000. Detailed histories revealed no association between the development of multiple myeloma and contact with Kepone, a chemical reported to have affected workers in a nearby community. The target area does contain a large number of industrial plants, with family residences in close proximity, and there are three that deal with lumber and millwork. Total protein examinations of 305 patients, 159 of whom came from the cluster area, revealed only one suspected case of multiple

REVIEW

myeloma; however, this person may have monoclonal gammopathy from another cause. (10 refs)

- 79-1289 Diet, Hormones, and Breast Cancer.** (Eng) Kent, S. (Woodstock, NY). *Geriatrics* 34(1): 83-90; 1979.

A review of recent literature suggests that reducing dietary fats may protect against breast cancer by altering prolactin levels. However, attempts to duplicate in humans the anti-breast cancer effect of prolactin control in rats have failed. (38 refs)

- 79-1290 Epidemiology of Breast Carcinoma.** (Ger) Margreiter, R. (Chirurgische Universitätsklinik, Anichstrasse 35, A-6020 Innsbruck, Austria). *Wien Med Wochenschr* 128(24): 747-752; 1978.

Epidemiological studies of breast cancer are reviewed with special regard to risk factors. The incidence in men is <1% of that in women, and breast carcinoma is very rare in women aged <20 yr. Unlike the trend in Japan and other Asiatic countries, the incidence increases with advancing age. Generally, it is highest in women at high socioeconomic levels. The incidence is especially high among white women in western countries. No relationship was found between breastfeeding and breast cancer, but the incidence is high among nuns. The incidence increases with increasing age at menopause, which indicates the involvement of endogenous hormones and suggests an etiological role for exogenous hormones, such as oral contraceptives. Nutrition and other environmental factors also play a role, because women emigrating from countries with a low incidence to countries with a high incidence develop breast cancer more frequently than the women who did not emigrate. Breast carcinoma is related to the consumption of animal fats and to obesity. Mothers and sisters of breast carcinoma patients have a twofold greater risk than women without breast cancer in their family. Particles similar to murine mammary tumor virus were found in the milk of breast cancer patients and their female relatives. Breast cancer risk was found to be two to four times as high in Japanese atomic bomb survivors who were exposed to about 90 rads than in the general population. Fibrocystic mastopathy increases breast cancer risk by a factor of 4. (87 refs)

- 79-1291 Smoking and Lung Cancer: The Problem of Inferring Cause.** (Eng) Burch, P. R. (Dept. Medical Physics, Univ. Leeds, Leeds, England). *J R Stat Soc A* 141(part 4): 437-477; 1978.

Studies of the associations between smoking and lung cancer and their connection with sex and country are reviewed. The data in these studies corroborate the pure constitutional and combined theories but conflict with the pure causal theory of lung cancer and smoking. The sex and age distributions of deaths from lung cancer, as recorded by the Registrar Gen-

eral of England and Wales for 1901 to 1970, were analyzed by 5-yr intervals. Most of the recorded increase in lung cancer deaths was in the higher age groups (>45 yr old). Analysis of the temporal trends for lung cancer does not support the idea that the tumors were caused mainly by changes in smoking habits. The trends in lung cancer mortality among British male doctors, many of whom are exsmokers, also do not support the theory of a causal association between smoking and lung cancer. The age patterns of death rates (1960-1961) in 26 national populations with a wide range of death rates were all similar when analyzed mathematically. This series of coincidences is unlikely to be accidental, and it suggests that the kinetics of onset and death from lung cancer are fairly uniform throughout the world. From the evidence it is argued that no definitive conclusions can be reached about the extent of any causal link between smoking and lung cancer. Any appreciable causal action is unlikely to involve initiating or promoting mechanisms, but precipitation of forbidden clones in genetically predisposed hosts is consistent with the age patterns of lung cancer. (103 refs)

- 79-1292 Malignant Ovarian Tumors.** (Ita) Mossetti, C. (I. Clinica Ostetrica e Ginecologica, Università di Torino, Turin, Italy); Compagnoli, C.; Gilli, V. *Minerva Ginecol* 30(12): 1111-1122; 1978.

Epidemiological studies of malignant ovarian tumors (OT) are reviewed. Serous carcinomas account for about 46% of all OT, solid carcinomas for 24%, endometrioid carcinomas for 15%, and mucinous carcinomas for 13%. The incidence of malignant OT is lowest in Spain (2.6/100,000) and Japan (2.8/100,000) and highest in Sweden (15.1/100,000). The incidence is highest in the age bracket 50-65 yr. Previous dysmenorrhea and endometriosis are more frequent in patients with OT than in the general population. The incidence of OT is higher in nullipara and single women and in subjects with blood Group A, but there is no relationship between a family history of these tumors or the development of obesity and OT. A history of parotitis is more common in tumor-free women than in tumor patients. The incidence of OT is higher in developed countries and in the upper socioeconomic classes than in underdeveloped countries and in the lower classes. (39 refs)

- 79-1293 Cancer of the Urinary Bladder--Epidemiology and Aetiology.** (Eng) Morrison, R. (Radiotherapy Dept., Hammersmith Hosp., London, England). *Urol Res* 6(4): 183-184; 1978.

Geographical variations in bladder cancer incidence and known etiological factors are reviewed. Available data suggest that the incidence is highest in England and Wales. The incidence is also high in Egypt, where the disease is associated with bilharzia. Substances possibly associated with bladder cancer include chemicals used in aniline dye manufacturing, caffeine, aromatic amines, phenacetin, cyclophosphamide, and substances in cigarette smoke. (15 refs)

- 79-1294 Dietary Factors in the Aetiology of Gastrointestinal Cancer.** (Eng) Cummings, J. H. (MRC Dunn Clinical Nutrition Center, Addenbrooke's Hosp., Trumpington St., Cambridge, England). *J Hum Nutr* 32(16): 455-465; 1978.

Current epidemiological evidence that supports a role of dietary factors in the etiology of gastrointestinal (GI) cancer is reviewed. Of the total cancer deaths occurring annually in England and Wales, 32% (approx 40,000) are due to GI cancers, mainly in the esophagus, stomach, pancreas, and large bowel. Nutritional factors have been implicated in the cause of each of these cancers, and they probably act by promoting the effect of carcinogens consumed in diet or produced by the metabolic processes of the gut or its flora. Esophageal cancer shows the most striking geographic variation in incidence of all cancers, and etiological factors clearly vary in different parts of the world. Although no specific carcinogen has been identified, epidemiological evidence suggests that a variety of dietary factors, both nutritional deficiencies and excesses, may promote the tumor-inducing effect of carcinogens. A highly regarded hypothesis is that the ingestion or formation in the stomach of nitrosamines causes gastric carcinoma. Nitrosamine formation is enhanced by dietary nitrite and nitrate ingestion and inhibited by low temperatures (2 C) and vitamin C. The presence of bile acids is thought to enhance or promote the carcinogenicity of substances in the large intestine, and increased fecal bile acid excretion has been correlated with increased animal fat intake. High protein diets have been related to increased colon cancer incidence, possibly due to the presence of bacterial protein metabolites such as ammonia, phenol, p-cresol, and tryptophan metabolites, which may be tumor promoters. Dietary fiber may be a protective factor in large bowel cancer. The main risks of pancreatic cancer may be related to dietary fat intake and cigarette smoking and, possibly, protein intake. (62 refs)

- 79-1295 Diet and Colon Cancer.** (Eng) Graham, S. (Bldg. 2, Room 313, Spaulding Quadrangle, Univ. New York at Buffalo, Buffalo, NY, 14261); Mettlin, C. *Am J Epidemiol* 109(1): 1-20; 1979.

The effects of dietary fiber, animal fats, and vegetables on the risk of colon cancer are reviewed, as are problems associated with measuring dietary habits. One epidemiologic study suggests that a frequent intake of fibrous foods is associated with a low risk of colon cancer. A greater body of data suggests that a decreased risk of colon cancer is associated with eating vegetables and an increased risk is associated with a high meat or beef diet. Inconsistencies in findings and a relative paucity of data make definite conclusions imprudent, however, and suggest the need for further inquiry. Laboratory studies will be needed, as will studies on the past eating habits of humans. Despite its crudeness, the interview approach

shows some promise of aiding in the latter studies and of shedding light on the epidemiology of colon cancer. (48 refs)

- 79-1296 Dietary, Environmental, and Hereditary Factors in the Development of Colorectal Cancer.** (Eng) Lipkin, M. (Dept. Medicine, Cornell Univ. Medical Coll., New York, NY). *Cancer Bull* 30(6): 196-201; 1978.

Studies concerning factors involved in the etiology of colorectal cancer are reviewed. There is strong evidence to indicate that environment has a role in the development of colorectal cancer, but the most important elements involved are unclear because of conflicting findings. Some investigators believe that metabolic products of biliary metabolism, low dietary fiber content, and bacterial and intestinal cellular enzymes are key factors in increasing colon cancer risk. This relationship is supported by studies of many populations, but there are conflicting reports, particularly studies carried out in Finland and in groups such as the Mormons and Seventh-Day Adventists. The development of colorectal cancer has been shown to be influenced by genetic predisposition. Recent findings have indicated that familial associations of colon cancer in the general population are higher than those in control groups, suggesting that inherited factors may have a greater role in the genesis of colorectal cancer than has been generally believed. Specific abnormalities have been observed in the cells and intestinal contents of individuals with a hereditary predisposition to colorectal cancer. These abnormalities, which are tabulated here, are now serving as indices for studies of high-risk population groups and studies attempting to define interactions between cells genotypically predisposed to neoplasia and carcinogenic or promotor elements. (57 refs)

- 79-1297 Concepts in the Etiology and Prevention of Large Bowel Cancer. The Role of Intestinal Microflora.** (Eng) Mastromarino, A. J. (Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX). *Cancer Bull* 30(6): 202-205; 1978.

Literature concerning the relationship between intestinal flora and large bowel cancer is reviewed. Epidemiologic and laboratory investigations have indicated that intestinal flora are involved in large bowel carcinogenesis. However, it is unlikely that the bacteria produce a carcinogen, although they may produce N-nitroso compounds. In addition, the flora produce secondary acid sterols that have demonstrated promoting activity in animal models and are found in increased concentrations in the feces of high-risk populations. It may be feasible to modify the enzymic activities of the gut flora and thereby modify their carcinogenic or cocarcinogenic potential. (44 refs)

- 79-1298 Enteric Microenvironment and Its Effect upon the Morbid Anatomy of the Colon: A Study of Colon Cancer, Its Precursors, and Its Companions in Hawaii Japanese.** (Eng) Stemmermann, G. N. (No affiliation given); Hayashi, T.; Yatani, R. *Pathol Annu* 13(1): 1-18; 1978.

Studies of colon cancer and other diseases of the colon in native Japanese and Hawaii Japanese are reviewed. Hawaii Japanese have colorectal cancer rates that are more than three times those of indigenous Japanese; the increased incidence is almost entirely accounted for by colonic tumors. Autopsy studies in indigenous and Hawaii Japanese indicate that both adenomatous and hyperplastic polyps and diverticulosis are more prevalent in Hawaii Japanese. The hyperplastic polyp is a more sensitive indicator of Westernization and has a closer site association with colon cancer than the adenomatous polyp. The bowel transit times are similar in both Japanese populations, indicating that there is no association between bowel transit time and the benign or malignant colorectal lesions common in Western societies. There are differences in the fecal flora in Japan and the US, eg, high *Escherichia coli* and *Streptococcus faecalis* counts are more typical of Japanese stools. Chemical analyses of feces showed no significant differences in the amounts of degraded and primary bile acids in the two populations and no significant increase in the amount of any unidentified bile salt in the Hawaii samples. In the *Salmonella typhimurium* mutagenicity assay, fecal samples from Hawaii Japanese showed more mutagenic activity than those from indigenous Japanese. It is concluded that differences in fecal bacteriology and mutagen activity exist between genetically similar populations at high and low risk for hyperplastic and adenomatous polyps and for carcinoma of the bowel and that these differences probably result from differences in diet and life style. (31 refs)

- 79-1299 Diagnosis and Management of Early Carcinoma of the Endometrium.** (Eng) Walton, L. A. (Div. Gynecologic Oncology, Dept. Obstetrics and Gynecology, Univ. North Carolina Sch. Medicine, Chapel Hill, NC, 27514). *J Natl Med Assoc* 70(5): 309-312; 1978.

The diagnosis and management of early carcinoma of the endometrium are reviewed. The incidence of this disease is increasing, and factors affecting this increase include usage of estrogens and oral contraceptives, delayed menopause, increasing longevity of women, and increasing use of diagnostic methods. (17 refs)

- 79-1300 Adenocarcinoma of the Prostate in Perspective.** (Eng) Bruce, A. W. (Dept. Urology, Kingston General Hosp., Kingston, Ontario K7L 2V7, Canada); Mahan, D. E. *Can Med Assoc J* 119(9): 1077-1084; 1978.

Adenocarcinoma of the prostate is reviewed with respect to epidemiology, current staging systems, and treatment. The disease is particularly common among American Blacks (78.8/100,000) and rare in Mongoloid races (3.2-4.3/100,000). Incidence increases with age. Many patients with clinically defined disease remain asymptomatic, whereas in others there is rapid deterioration. The American Urological System is recommended for staging because of its ability to reflect changes in the biologic behavior of the neoplasm. Rectal examination of the prostate and adequate biopsy provide the most accurate information on extent of local spread and histopathology. Pedal lymphangiography has not proved accurate for assessing lymphatic spread in early carcinoma of the prostate. Pelvic lymphadenectomy is done in many centers prior to radical surgery or radiotherapy because it provides accurate information on the extent of lymph node involvement. Radionuclide bone scanning is far more sensitive for detecting bone metastases than roentgenographic techniques, but it is nonspecific and fails to detect very early microscopic bone involvement. Immunologic methods for the analysis of prostatic acid phosphatase have proved superior to enzymatic methods used previously. (88 refs)

- 79-1301 Occupational Cancer Risk (Letter to Editor).** (Eng) Rall, D. P. (Natl. Inst. Environmental Health Sciences, P.O. Box 1223, Research Triangle Park, NC, 27709). *Science* 203(4377): 224-226; 1979.

Responses to a previous letter containing various industry-generated criticisms of the Department of Health, Education, and Welfare draft report "Estimates of the fraction of cancer in the United States related to occupational factors" are presented. The purpose of this report was to demonstrate that a careful consideration of the multifactor etiology of most cancers would indicate that occupational exposures play a more significant role in the onset of this disease than has been generally recognized. (2 refs)

- 79-1302 Asbestos and Mesothelioma: A Review.** (Eng) Kannerstein, M. (No affiliation given); Churg, J.; McCaughey, W. T. *Pathol Annu* 13(1): 81-129; 1978.

The properties and biological effects of asbestos are reviewed with emphasis on its association with mesothelioma and on the diagnosis and pathology of the disease. Clinical and epidemiologic studies have associated all types of asbestos with asbestosis and carcinoma of the lung. Asbestos is the only substance that has been shown to have an epidemiologically meaningful association with mesothelioma. The incidence of mesothelioma has increased strikingly since the 1950's, with nearly all cases being in persons occupationally exposed to asbestos. In most cases the process is primarily

in one cavity, and a pleural origin is more common than a peritoneal one. Metastasis is frequent but it is not generally extensive. The microscopic features of mesothelioma range extensively from the pure epithelial to the mesenchymal form, with a spectrum of intermediate and combined forms. In diffuse malignant mesothelioma, there is a greater multiplicity of cell types and patterns at any stage of differentiation than in most neoplasms. A hyaluronic acid concentration of $> 120 \mu\text{g}$ in mesotheliomatous effusions is suggestive of mesothelioma; when coupled with suggestive cytology or histology, this finding may make the diagnosis more certain. The incidence of mesothelioma is expected to reach a peak in the 1980s. Although the existence of a cancer hazard associated with general asbestos air pollution has not been proved, it has not been excluded. (161 refs)

- 79-1303 Nature and Nurture in the Disease Patterns of Africa. The Twentieth Maude Abbott Lecture.** (Eng) Hutt, M. S. (No affiliation given). *Pathol Annu* 13(1): 19-27; 1978.

The epidemiology of three dissimilar diseases, Burkitt's lymphoma (BL), tropical splenomegaly syndrome (TSS), and endomyocardial fibrosis of Davies (EMF), in Uganda is reviewed. All three diseases are extremely rare in the mountainous areas of Southwest Uganda and in Rwanda and Burundi. In the Kampala area of Uganda, both TSS and EMF are much more common in immigrant Rwandans and related tribes than in the indigenous tribes. There is no differ-

ence in the frequency of BL in children in these two tribal groups, but most adults with BL are immigrants to Uganda. Mapping of the distribution of BL led to the suggestion that the tumor is related to *Plasmodium falciparum* malaria. In addition, patients with BL have a lower frequency of the sickle cell trait than controls. Thus, a genetic factor, by providing protection against malaria possibly by virtue of the high fetal Hb content in the RBC, appears to provide some protection against BL. Malaria may produce an immunologically susceptible host who reacts in an unusual way to some other causative agent. In the case of BL, the causative agent appears to be Epstein-Barr virus. The importance of genetic factors is, however, clearly shown by the protective effect of the sickle cell trait against malaria. (40 refs)

- 79-1304 The State of the Environment: Selected Topics 1977.** (Eng) Governing Council (United Nations Environment Program, Nairobi, Kenya). *Environ Int* 1(4): 205-218; 1978.

The ozone layer, environmental cancers, land loss and soil degradation, and firewood are discussed in this first annual report prepared by the Executive Director of the United Nations Environment Program. In an overview designed for the layman, most pertinent facets of the environmental cancer problem, including regional differences, occupational, drug, and chemical exposures, and prospects of cancer control are touched upon. (13 refs)

CHEMICAL CARCINOGENESIS

- 79-1305 Assay of 855 Test Chemicals in Ten Tester Strains Using a New Modification of the Ames Test for Bacterial Mutagens.** (Eng) McMahon, R. E. (Lilly Res. Labs., Indianapolis, IN, 46206); Cline, J. C.; Thompson, C. Z. *Cancer Res* 39(3): 682-693; 1979.

A method is described that allows assessment of the mutagenic potential of chemicals in eight histidine auxotrophs of *Salmonella typhimurium* and two tryptophan auxotrophs of *Escherichia coli* over a 10,000-fold concentration range with or without metabolic activation. This procedure was used to test 855 chemicals, 182 of which were found to be mutagenic for one or more of the tester strains. Among the mutagenic compounds were 20% of 299 chemicals used in chemical manufacturing or laboratory synthesis and 8% of 361 organic chemicals synthesized for evaluation as potential pharmaceutical or agricultural products. *S. typhimurium* strain TA100 was the most sensitive tester strain, but it was not useful for distinguishing between frameshift and base-substitution mutagens. Strains TA98 and TA1538 were efficient and reliable detectors of frameshift mutagens. Base-substitution mutagens were more reliably detected by *E. coli* strains WP2 and WP2 *uvrA* than by *S. typhimurium* strains G46 and TA1535. Testing mutagens by concentration gradient procedures can be used to indicate: the activity spectrum in tester strains; frameshift vs base-substitution mutagens; the minimal concentration at which auxotroph growth is inhibited; and the minimal concentration at which mutagenicity is observed. (15 refs)

- 79-1306 The *Salmonella* Mutagenicity Assay: Recommendations.** (Eng) de Serres, F. J. (Office Associate Director Genetics, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC); Shelby, M. D. *Science* 203(4380): 563-565; 1979.

Recommendations are put forth to provide guidelines for conducting the *Salmonella* mutagenicity assay, and they constitute minimum criteria by which reports of mutagenicity testing in the *Salmonella* plate assay can be evaluated. Strains TA1535, TA1537, TA1538, TA98, and TA100 should be used for routine testing. Overnight cultures of bacterial strains that have just reached a density of $1-2 \times 10^8$ viable cells/ml are most desirable for mutagen testing. Standard procedures for confirming the histidine requirement, deep-rough character, and UV sensitivity of tester strains are satisfactory, but tests for the presence of the R factor, which confers ampicillin resistance in strains TA100 and TA98, can be conducted more conveniently by using commercially available filter-paper disks containing 10 μ g ampicillin. Stock cultures should be checked periodically to ensure that close to 100% of the bacteria contain the R factor. The Aroclor 1254-induced rat liver S-9 preparation is the activation mix

of choice for routine screening. A minimum of two plates per dose level and an incubation period of 48-72 hr are recommended. Dose levels of 0.2 μ g-5 mg/plate should be tested. Preincubation is recommended in cases in which results from the standard plate assay are inconclusive. Negative and positive controls and controls for S-9 sterility should be run with each experiment. Test reports should include the means and indications of variability of the plate counts for the negative control, the positive controls, and each dose of the test compound. (2 refs)

- 79-1307 Isolation of Mutagens from Bacterial Nutrients Containing Beef Extracts.** (Eng) Vithayathil, A. J. (Center Biology Natural Systems, Washington Univ., St. Louis, MO, 63130); Commoner, B.; Nair, S.; Madyastha, P. *J Toxicol Environ Health* 4(1): 189-202; 1978.

Investigation was made of the slight augmentation of the mutation of *Salmonella typhimurium* strains TA1538 and TA98 in the presence of microsomes in the standard Ames mutagenicity test. The effect was considerably amplified in a modification of the Ames test using a liquid-culture system. By using this system and a series of extraction and thin-layer chromatography experiments, it was determined that the increased mutagenicity is caused by the presence, in the nutrient broth that is included in the bacterial inoculum added to the test plate, of substances that are converted by the microsomal enzyme system to actively mutagenic metabolites. Bacterial nutrients that include an extract prepared from beef muscle commonly contain on the order of 2.5 ppm of organic substances that are highly mutagenic in the *Salmonella* test system. These data suggest, therefore, that previously undetected presumptive carcinogens may be widely present in beef or in food preparations derived from it at a concentration sufficient to cause concern. (7 refs)

- 79-1308 Radiobiological Techniques Applied to Environmental Problems.** (Eng) Hahn, G. M. (Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305). *Radiat Res* 76(3): 459-470; 1978.

The application of specific cellular radiobiological techniques to toxicologic drug testing is illustrated by experiments utilizing Chinese hamster (HA 1) cells in culture under a variety of conditions. These techniques are useful not only in dose-response considerations of cell survival, but also in determining rate of mutagenicity and oncogenicity. Two specific techniques use the kinetics of recovery from potentially lethal damage as a possible, rapid means of assaying error-prone repair and Arrhenius theory as an aid in pinpointing specific mutagenic or carcinogenic reactions. Pitfalls involved when drug dose-effect relationships are determined in

tissue culture include the binding of drugs to growth surfaces, decay of drug activity, activity of agents released from inactivated cells, and the need for active intracellular metabolism for the correct estimation of some drug effects. Short- and long-term drug stability may be affected by pH or by the initial drug concentration. A drug may not exert its usual cytotoxic characteristics until after it is appropriately metabolically modified by the cell itself. If this metabolism is interfered with, the effectiveness of the drug may be reduced. It is hoped that careful observance of these subtle effects will avoid erroneous conclusions about important features of dose-response curves. (13 refs)

- 79-1309 Exploratory Techniques for the Determination of Potential Dose-Response Relationships Between Human Health and Air Pollution.** (Eng) Page, W. P. (Dept. Economics, West Virginia Univ., Morgantown, WV, 26506); Fellner, W. *J Environ Econ Manage* 5(4): 376-389; 1978.

The usefulness of selected multivariate statistical techniques, ie, factor analysis/correlation and canonical correlation techniques, for exploring new dose-response relationships between human health and air pollution was evaluated. Results obtained using these techniques were compared with those established in the literature through hypothesis testing procedures or laboratory work. This use of multivariate techniques is pretheoretical and should be interpreted as suggesting relationships that warrant further investigation with more traditional methodologies. Diseases for which data sets were examined included gastrointestinal, breast, respiratory system, urinary system, thyroid, and pleural cancer. Disease states were correlated with NO₂, SO₂, and SO₄ as pollutants. Using factor analysis/correlation techniques, highly significant results appeared between SO₂, SO₄, and gastrointestinal cancer and between NO₂ and breast cancer. Using canonical correlation techniques, positive correlations were obtained between SO₂ and SO₄ and gastrointestinal cancer and respiratory system cancer. The results conformed well to those of previously reported regression studies and lend credence to the use of these pretheoretical statistical methods. (18 refs)

- 79-1310 Determining the Distribution Pattern of Cadmium in the Human Liver.** (Ger) Kinkeldey, G. (Lehrstuhl Allgemeine und Kommunale Hygiene, Humboldt-Universität zu Berlin, Otto-Grotewohl-Strasse 1, DDR-108 Berlin, E. Germany). *Z Gesamte Hyg* 24(12): 927-929; 1978.

The hepatic cadmium distribution pattern was determined in samples taken from 13 sites in each of 10 livers taken from men aged 50-80 yr; the livers had no macroscopically visible pathological changes. The mean Cd concentration for each liver ranged from 1.22 to 1.59 µg/g. The variations were not statistically significant within one organ or from one organ to another. Sites of increased Cd concentration were found in all livers, but they varied from liver to liver; ie, there was

no preferred site for determining the Cd level in the liver. (5 refs)

- 79-1311 Structural and Histochemical Study of Ferridextran-induced LEW/CUB Tumours FLA, FLB, FLC, and FL.** (Eng) Elleder, M. (First Dept. Pathology, Faculty General Medicine, Charles Univ., Prague, Czechoslovakia); Jirasek, A.; Kren, V. *Folia Biol (Praha)* 24(6): 387-388; 1978.

The morphology and histochemical features of ferridextran-induced LEW/CUB tumors FLA, FLB, FLC, and FL were studied. During the latent period, the only recognizable histological structures were deposits of the iron pigment in the macrophages and extracellular spaces. The tumor was characterized as an anaplastic pleomorphic sarcoma, lacking any special histological pattern. The cytoplasm of the tumor cells was markedly oxyphilic and always recognizable. Individual tumor types could not be distinguished morphologically because the features were so variable. The following ultrastructural features were relatively frequent: (1) ribosomes, either free in the cytoplasm or bound in the rough endoplasmic reticulum; (2) lysosome-like dense bodies, often seen in the vicinity of the Golgi apparatus; and (3) coated vesicles situated beneath the cell membrane. True desmosomes were observed only occasionally and no production of collagen fibers was detected. Dehydrogenase activities were markedly decreased or absent in the necrotic areas. In tumor cells bordering this area, the activity of all dehydrogenases examined was moderately increased. No structural or histochemical features were found that helped to determine tumor histogenesis, and no clear-cut differences were observed that could be linked to the varying biological behavior of the different tumors. (1 ref)

- 79-1312 Lack of Cytogenetic Effects in Mice or Mutations in Salmonella Receiving Sodium Fluoride.** (Eng) Martin, G. R. (Lab. Developmental Biology and Anomalies, Natl. Inst. Dental Res., NIH, Bethesda, MD, 20014); Brown, K. S.; Matheson, D. W.; Lebowitz, H.; Singer, L.; Ophaug, R. *Mutat Res* 66(2): 159-167; 1979.

There was no evidence of an increased frequency of chromosomal aberrations in the bone marrow or testis cells of Swiss-Webster and BALB/c mice given either 50 ppm fluoride in the drinking water over several generations or 100 ppm for 6 wk, compared with untreated controls. Fluoride was not mutagenic in a *Salmonella typhimurium* mutagenesis assay over a range of 0.1-2,000 µg fluoride per plate. (22 refs)

- 79-1313 Quantitative Studies of In Vitro Morphological Transformation of Syrian Hamster Cells by Inorganic Metal Salts.** (Eng) DiPaolo, J. A. (Lab. Biology, NCI, Bethesda, MD, 20014); Casto, B. C. *Cancer Res* 39(3): 1008-1013; 1979.

Twelve metal compounds were tested for transforming ability by direct application to Syrian hamster embryo cells (HEC) that had been seeded for colony formation. Four of these compounds were also tested by a transplacental in vivo-in vitro approach. Petri dishes were seeded with 300 HEC from a secondary culture plus an irradiated feeder layer of 6×10^4 HEC. Chemicals (0, 2.5, 5, 10, or 20 $\mu\text{g}/\text{ml}$) were added 24 hr later. Dishes were fixed and stained 9 days after seeding. Morphological transformation was induced by inorganic salts of Ni (2 different Ni salts), Cd, Cr, Be, and As, but not Fe, Ti, Tu, Zn, Al, and NiS amorphous. No transformation was observed in untreated controls. Lethality, indicated by a reduction in cloning efficiency, occurred with both carcinogenic and noncarcinogenic metal salts. Transformation of HEC was also observed after transplacental exposure to inorganic salts of Ni, Be, Cr, and Cd (pregnant hamsters were injected with 2.5 or 5 mg/g ip on gestation day 11). The transformed colonies had a variety of morphologies that reflected the cell types present in early passages and that were identical to those observed after organic carcinogen exposure. There are animal data for the carcinogenicity of all the positive metals except As. Acceptable evidence for human carcinogenicity is available for all positive metals except Cd, although there is a possibility of a relationship between occupational exposure to Cd and prostatic cancer. Although Cd and Cr were the most potent transforming agents in terms of dose-response relationships, the comparative potency of the metals could not be determined, since it would depend on the ionization potential of the metal, the inorganic salt form, and the possible biointeractions of the various metals. (49 refs)

- 79-1314 Carcinogenicity of Antitumor *cis*-Platinum(II) Coordination Complexes in the Mouse and Rat.** (Eng) Leopold, W. R. (McArdle Lab. for Cancer Res., Univ. Wisconsin Center Health Sciences, Madison, WI, 53706); Miller, E. C.; Miller, J. A. *Cancer Res* 39(3): 913-918; 1979.

cis-Dichlorodiammineplatinum(II) [DDP: total of 54-108 micromoles (μmol)/kg given in 5-19 weekly ip injections], *cis*-dichlorobis(cyclopentylamine)platinum(II) (DCP: total of 108 or 433 $\mu\text{mol}/\text{kg}$ given in 10 weekly ip injections), *cis*-dichlorobis(pyrrolidine)platinum(II) (DPP: 2.5 mg/wk for 6 wk, sc), and ethyl carbamate (5,600 $\mu\text{mol}/\text{kg}$ given as a single ip injection) were tested for their carcinogenicity in female CD-1 and A/Jax mice and male Fischer rats and for their mutagenicity in *Salmonella typhimurium*. All mice given 103-108 $\mu\text{mol}/\text{kg}$ DDP developed lung adenomas within 8 mo, the efficiency of tumor induction being similar whether the DDP was injected in 0.85% NaCl soln or as a suspension in trioctanoin. Of the mice given 433 $\mu\text{mol}/\text{kg}$ DCP, 95% developed adenomas. Both DDP and DCP induced more adenomas per micromole of compound administered than did ethyl carbamate. DDP alone did not induce any gross skin tumors, but 50% of the mice treated topically with 0.6% croton oil while being given ip DDP developed papillomas at the site of application of the croton oil. Mice treated with croton oil alone also did not develop any skin tumors. Of the mice given 2 g/kg ethyl carbamate, 61% developed papil-

lomas within 30 wk. DPP and, to a lesser extent DCP, induced sarcomas at the site of injection in rats as well as some metastasizing sarcomas and an epidermoid carcinoma of Zymbal's gland. DDP, DCP, and DPP were mutagenic for *S. typhimurium*, with DDP being the most active. Treatment of patients with platinum antitumor complexes may impose a risk of secondary tumor induction in long-term survivors. (34 refs)

- 79-1315 Synthesis and Therapeutic Testing of Mono- and Dialkyl Esters of Pentetic (Diethylenetriaminepentaacetic) Acid for Decorporation of Polymeric Plutonium.** (Eng) Guilmette, R. A. (Inhalation Toxicology Res. Inst., Albuquerque, NM, 87115); Parks, J. E.; Lindenbaum, A. *J Pharm Sci* 68(2): 194-196; 1979.

A series of partially esterified derivatives of pentetic acid (diethylenetriaminepentaacetic acid) were prepared in an attempt to promote increased removal of insoluble colloidal forms of plutonium from the liver, compared with that removed by pentetic acid alone. The dimethyl, diethyl, dibutyl, dioctyl, and monoethyl esters of pentetic acid were injected iv into female B6CF₁/Anl mice as their calcium chelates in saline 5 days after iv injection of polymeric Pu (1.0 $\mu\text{Ci}/\text{kg}$). None of the esters were effective in removing Pu from the liver. All the esters removed approx 20% of the Pu in the skeleton. When the esters were given together with pentetic acid, only the dioctyl ester showed enhanced removal of Pu compared with pentetic acid alone. All of the esterified compounds were more acutely toxic than pentetic acid. The small increase in effectiveness and the increased acute toxicity indicate that these esters are not practical in Pu decorporation therapy. (20 refs)

- 79-1316 Induction of Duodenal Serotonin Production by Dietary Sodium Selenite and Aflatoxin B₁.** (Eng) Lator, J. H. (Dept. Biology, Virginia Commonwealth Univ., Richmond, VA, 23284); Kimbrough, T. D.; Llewellyn, G. C. *Food Cosmet Toxicol* 16(6): 611-613; 1978.

Male Mongolian gerbils were fed diets supplemented with 5 ppm sodium selenite (Na_2SeO_3), 12.8 ppm aflatoxin B₁ (AFB₁), or Na_2SeO_3 + AFB₁ for 12 wk. The animals were then killed and their duodenal serotonin levels were determined. All three dietary supplements induced significant serotonin increases. The duodenal serotonin level in controls was 6 $\mu\text{g}/\text{g}$, compared with 12 $\mu\text{g}/\text{g}$, 24 $\mu\text{g}/\text{g}$, and 72 $\mu\text{g}/\text{g}$ in the animals given Na_2SeO_3 , Na_2SeO_3 + AFB₁, and AFB₁, respectively. The increase in the Na_2SeO_3 group may have been due to the metabolism of additional tryptophan absorbed from the gastrointestinal tract or to the increased activity of an enzyme that accelerates the rate of serotonin biosynthesis. The increase in the AFB₁ group could be explained partially by normal metabolism of higher available levels of tryptophan or by decreased peristalsis resulting in feed remaining longer in the intestinal tract and leading to increased digestion and absorption. The intermediate result shown by the

group given the combined diet may represent a combination of the mechanisms involved in the other two test groups. It is concluded that AFB₁, Na₂SeO₃, interact with serotonin metabolism both separately and in combination. (21 refs)

- 79-1317 Mutagenic Activity of Selenium Compounds.** (Eng) Noda, M. (Dept. Microbiology, Keio Univ. Sch. Medicine, Tokyo, Japan); Takano, T.; Sakurai, H. *Mutat Res* 66(2): 175-179; 1979.

Selenate and selenite were found to be weakly mutagenic in two bacterial assay systems: Kada's *rec* assay and Ames's Salmonella assay. In the Ames test, base-pair substitution occurred with both selenate and selenite (0.05 and 0.2 revertant/nanomole, respectively). (13 refs)

- 79-1318 Exposure of DNA to Two Carcinogens, Dimethyl and Diethylsulfate (Meeting Abstract).** (Eng) Kubinski, H. (Univ. Wisconsin, Madison, WI, 53706); Fiant, M.; Konopa, G.; Kubinski, Z. O. *Fed Proc* 38(3, part 1): 502; 1979. (no refs)

- 79-1319 Phenotypic Expression Time of Mutagen-induced 6-Thioguanine Resistance in Chinese Hamster Ovary Cells (CHO/HGPRT System).** (Eng) O'Neill, J. P. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Hsie, A. W. *Mutat Res* 59(1): 109-118; 1979.

The phenotypic expression time of ethyl methanesulfonate (EMS)-induced 6-thioguanine resistance in Chinese hamster ovary cells [CHO/hypoxanthine-guanine phosphoribosyltransferase (HGPRT) system] was studied using trypsin, EDTA, or ethylene glycol bis(β -aminoethyl ether)-N,N,N',N'-tetraacetic acid (EGTA) for cell removal. The effect of 30 μ M hypoxanthine in the medium was also determined. Hypoxanthine had little or no effect on transcription rates or on the intracellular stability of the HGPRT enzyme, and max stable mutation frequencies were observed at 7 days' expression time using trypsin, EDTA, or EGTA. The duration of expression time was affected by subculture interval, and CHO cells could be maintained for 3 days between subculture during phenotypic expression with no detrimental effects on mutant expression. Continual cell growth and division, uninterrupted by subculture, resulted in a shortening of the expression time, max expression being obtained after six to eight cell divisions. Mutation induction and fixation were apparently completed during the initial three to four cell divisions, and completion of phenotypic expression did not require continued cell division thereafter. The data suggest that in the CHO/HGPRT system, expression time is a constant that is independent of the mutagenic agent and dose. (16 refs)

- 79-1320 The Control of *Plasmopara viticola* with the 1:1 Complex of Zineb with 2-(2-Aminoethylamino)ethanol and the Potential Effect of the Use of This**

Complex on Ethylenethiourea Residues. (Eng) Clifford, D. P. (Dow Chemical Co. Ltd., Crossbank Road, King's Lynn, Norfolk, England); Bruyns-Haylett, J. P. *Pestic Sci* 9(5): 493-495; 1978.

A 1:1 complex of the metal dithiocarbamate (DTC) zineb with 2-(2-aminoethylamino)ethanol was more active than zineb in greenhouse and field trials against the grape downy mildew *Plasmopara viticola*. Potentiation of the activity of metal DTC's, which tend to decompose to the carcinogen ethylenethiourea, (ETU), may allow ETU levels to be reduced by permitting a reduction in the amount of DTC needed to control a fungal pathogen. (14 refs)

- 79-1321 Enhanced Metabolism and Mutagenesis of Nitrosopyrrolidine in Liver Fractions Isolated from Chronic Ethanol-consuming Hamsters.** (Eng) McCoy, G. D. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Chen, C. B.; Hecht, S. S.; McCoy, E. C. *Cancer Res* 39(3): 793-796; 1979.

The effect of chronic ethanol consumption (35% of the total caloric intake for 4 wk) on the ability of isolated liver fractions to metabolize the carcinogen N-nitrosopyrrolidine (NPY) was studied using male Syrian golden hamsters. Chronic ethanol consumption markedly increased the content of cytochrome P-450 and the activities of aniline hydroxylase and NPY α -hydroxylase in liver microsomes. NADPH-cytochrome c reductase was increased to a lesser extent, and the activities of glucose-6-phosphatase and benzo(a)pyrene hydroxylase were not affected. The postmitochondrial supernatants from ethanol-consuming animals were 4- to 5-fold more effective in converting NPY to a mutagen for *Salmonella typhimurium* than were those from control animals. It is concluded that α -hydroxylation is probably the mechanism whereby NPY is converted to a mutagen and that this pathway can be induced by ethanol. (38 refs)

- 79-1322 Factor VIII Content as Evidence for Endothelial Origin of Vinyl Chloride Associated Liver Angiosarcoma (Meeting Abstract).** (Eng) Fortwengler, H. P. (Univ. Louisville Sch. Medicine, Louisville, KY, 40232); Jones, D.; Tamburro, C. H.; Espinosa, E. *Fed Proc* 38(3, part 1): 999; 1979. (1 ref)

- 79-1323 The Clinical Features of Hepatic Angiosarcoma: A Report of Four Cases and a Review of the English Literature.** (Eng) Locker, G. Y. (Clinical Pharmacology Branch, NCI, Bldg. 10, Room 6N119, 9000 Rockville Pike, Bethesda, MD, 20014); Doroshow, J. H.; Zwelling, L. A.; Chabner, B. A. *Medicine (Baltimore)* 58(1): 48-64; 1979.

The clinical features and treatment of hepatic angiosarcoma are discussed based on four case reports and a review of 99 cases from the English literature. An apparent etiology was

identified in 43/103 cases: vinyl chloride in 22, thorotrast in 15, arsenicals in 2, radium in 1, and underlying hemochromatosis in 3. The tumor was most common in middle-aged men. The most common symptoms were abdominal pain, weakness, fatigue, and wt loss, and the most common presenting physical findings were hepatomegaly, ascites, and jaundice. Abnormalities in liver function tests, thrombocytopenia, and elevated prothrombin time were frequent laboratory findings. Arteriography was a valuable diagnostic tool, as was open biopsy at surgery. However, liver biopsy was accompanied by both morbidity and mortality, especially related to bleeding. Problems encountered during the clinical course included hepatic failure, intraabdominal and gastrointestinal bleeding, and peripheral destruction of blood elements. The median survival time from the first symptom was 5.5 mo, and only 3% of the patients lived > 2 yr. (144 refs)

79-1324 In Vivo Trapping of a Vinyl Chloride Metabolite by Means of 3,4-Dichlorobenzethiol.

(Eng) Muller, G. (Institut für Staublungenforschung, Westring 10, D-4400 Münster, W. Germany); Norpeth, K.; Owzarski, W. *Int Arch Occup Environ Health* 42(2): 137-139; 1978.

A method for trapping metabolites of vinyl chloride (VC) and 2,2'-dichlorodiethylether (DDE) is reported. Rats treated with VC and 3,4-dichlorobenzethiol excrete S-2(3,4-dichlorothiophenyl)acetic acid in the urine. The structure of the compound was confirmed by gas chromatography-mass spectrophotometry. Similar results were obtained with DDE. Thus, the formation of ultimate carcinogens from nonelectrophilic precursors can be proved by the use of nucleophilic trapping agents both in vitro and in vivo. (9 refs)

79-1325 Head-Space Gas-Chromatographic Analysis of Vinyl Chloride Monomer in Rat Blood and Tissues.

(Eng) Zuccato, E. (Istituto di Ricerche Farmacologiche "Mario Negri", Via Eritrea 62, 20157 Milan, Italy); Marcucci, F.; Fanelli, R.; Mussini, E. *Xenobiotica* 9(1): 27-31; 1979.

Vinyl chloride monomer (VCM) levels in rat blood and tissues were measured by a head-space gas chromatograph fitted with a flame ionization detector. Male CD rats were given VCM (1, 5, or 10 mg/kg iv or 10 mg/kg po) and killed 1-120 min later. VCM deposition was determined in blood, liver, kidney, brain, and lung. VCM was distributed rapidly after iv administration; blood had the highest concentration at 1 min, but brain and kidney levels attained equilibrium with blood levels within 2 min of injection. VCM in both blood and tissues was no longer detectable at 15 min for the highest iv dose and at 4 min for the lowest. VCM concentrations were lower in the lung than in blood and other organs at all times. Liver concentrations were generally lower than those of brain and kidney. VCM reached a high concentration in blood at 5 min after po administration, indicating rapid absorption from the gastrointestinal tract. At 60 min it was detectable

only in traces, and at 120 min it was no longer detectable. VCM concentrations in the liver were higher than those in blood up to 20 min, but they decreased faster than those in the other tissues, suggesting that metabolism by the liver may determine the disposition of VCM. The technique described is sensitive to 5 nanograms (ng)/ml VCM in blood and 30 ng/g in tissues. (15 refs)

79-1326 Carcinogenicity of Vinyl Chloride and Vinylidene Chloride.

(Eng) Lee, C. C. (Midwest Res. Inst., 425 Volker Blvd., Kansas City, MO, 64110); Bhandari, J. C.; Winston, J. M.; House, W. B.; Dixon, R. L.; Woods, J. S. *J Toxicol Environ Health* 4(1): 15-30; 1978.

The effects of exposure to 50, 250, or 1,000 ppm vinyl chloride (VC) or 55 ppm vinylidene chloride (VDC) for 6 hr/day, 5/days/wk, were studied in albino CD-1 mice and CD rats. The animals were killed after 1, 2, 3, 6, 9, or 12 mo. Bronchioloalveolar adenomas developed in 12/63, 22/63, and 48/69 mice exposed to 50, 250, and 1,000 ppm VC, respectively. Bronchioloalveolar adenomas developed in 6/35 animals exposed to VDC. Three of 29, 23/63, and 31/69 mice exposed to 50, 250, and 1,000 ppm VC, respectively, developed hemangiosarcomas (HS) in the liver. In the mice exposed to VDC, HS developed in the livers of two males and one female. Mammary gland tumors occurred in 9/34, 3/34, and 13/36 female mice exposed to 50, 250, and 1,000 ppm VC respectively, and they included ductular adenocarcinomas and squamous and anaplastic cell carcinomas with metastasis to the lung. Malignant lymphomas were found in various organs of mice exposed to VC but not in any of the mice exposed to VDC. Twelve of 70 and 21/70 rats exposed to 250 and 1,000 ppm VC, respectively, developed HS in the liver; 3/34 female rats exposed to 250 ppm VC and 13/70 rats exposed to 1,000 VC also developed HS in the lung. Two of 36 male rats exposed to VDC developed HS in the mesenteric lymph node or sc tissue. It is concluded that VC is highly carcinogenic in mice; the incidence and severity of the tumors increased with dose and length of exposure. Rats were more resistant to the carcinogenic effects of VC and VDC. (26 refs)

79-1327 Role of Liver Glutathione in 1,1-Dichloroethylene Metabolism and Hepatotoxicity in Intact Rats and Isolated Perfused Rat Liver.

(Eng) Reichert, D. (Institut für Pharmakologie, Universität Würzburg, Versbacher Strasse 9, D-8700 Würzburg, W. Germany); Werner, H. W.; Henschler, D. *Arch Toxicol (Berl)* 41(3): 169-178; 1978.

The role of liver glutathione in the metabolism and hepatotoxicity of 1,1-dichloroethylene (vinylidene chloride: VDC) was studied after po administration of 1,000 mg/kg VDC to female Wistar rats and after perfusion of isolated rat livers with 26.0 µg/ml VDC. After po administration, VDC lowered the liver glutathione concentration in a dose-dependent fashion. Glutathione levels dropped to approx 30% of control values after 4 hr; however, these levels returned to control

values within 24 hr. Addition of VDC to the perfusate caused a 23% drop in the glutathione concentration in isolated livers after 90 and 180 min of perfusion. The decrease was more pronounced when diethyl maleate, a mercapturic acid precursor, was also added to the perfusate. VDC metabolism was lowered by 18% after diethyl maleate-induced depletion of the reduced liver glutathione pool in livers from fed, but not fasted, rats. Increases in the extra-hepatic glutathione pool did not produce a change in total VDC conversion. A VDC-induced reduction in liver glutathione did not increase liver SGOT or SGPT levels in the perfused liver, but the lactate/pyruvate ratio was significantly increased. These findings indicate that there is no correlation between the liver glutathione level and the hepatotoxicity of VDC in fasted rats. (22 refs)

79-1328 Exchange of Comments: Analytical Methods of Bis(chloromethyl) Ether in Air (2 Letters to Editor). (Eng) Yao, C. C. (Poly-Tech Labs., Inc., P.O. Box 15623, Orlando, FL, 32858); Zollinger, H.; Kallos, G. J.; Solomon, R. A.; Tou, J. C. *Anal Chem* 51(2): 299-302; 1979.

The validity of the derivative method for determining levels of bis(chloromethyl) ether (BCME) in air, in which BCME is converted by trichlorophenol and methoxide in methanol into a derivative that is then assayed by gas chromatography, is questioned. In a reply, proponents of the method state that factual data supporting the criticism are not presented and that the derivative method, which is specifically designed to determine ppb levels of BCME in air, has been repeatedly shown to be chemically and technically sound. (30 refs)

79-1329 Cytogenetic Investigation of Occupational Exposure to Epichlorohydrin. (Eng) Picciano, D. (Office Carcinogen Identification and Classification, Occupational Safety and Health Admin., Dept. Labor, Washington, DC, 20210). *Mutat Res* 66(2): 169-173; 1979.

Cytogenetic studies were conducted on peripheral lymphocytes from 93 workers currently exposed to epichlorohydrin and from 75 persons seen for preemployment examination. A total of 200 cells/individual were scored for chromatid breaks, chromosome breaks, marker chromosomes, severely damaged cells, and total abnormal cells. Cells from the epichlorohydrin workers had a marked increase in all five categories of aberrations, compared with those from the nonexposed individuals. The difference was statistically significant in all categories except marker chromosomes. These results confirm those of a previous cytogenetic study of 35 epichlorohydrin-exposed workers. (9 refs)

79-1330 Lack of Effect of Trichloropropene Oxide on Benzo(a)pyrene Tumor-initiating Activity on Mouse Skin. (Eng) Alexandrov, K. (Institut de Recherches Scientifiques sur le Cancer, 94800-Villejuif, France); Dan-

sette, P. M.; Flodrops, M.; Frayssinet, C. *Eur J Cancer* 15(1): 77-83; 1979.

The effect of the epoxide hydratase inhibitor 1,1,1-trichloro-2,3-propene oxide (TCPO) on the induction of skin cancer by benzo(a)pyrene (BP) was studied in male Swiss mice. BP [0.1 micromole (μ mole)] with or without TCPO (2 μ mol) was applied either once (day 1) or twice (days 1 and 3) to the skin of the backs of mice shaved 24 hr earlier. Thereafter, the mice were given weekly applications of croton oil (20 μ l of 1% soln in acetone for 50 wk). Skin tumors started to appear 15 wk after initiation of the mice in the groups given BP with or without TCPO. The skin microsomal epoxide hydratase activity [48-52 picomoles of benzo(a)pyrene-4,5-diol/min/mg] was inhibited at 3 hr, but not at 16 or 24 hr, after application of BP with or without TCPO. TCPO had no in vitro effect on the 3 H-BP binding to epidermal DNA 24 hr after application of BP. Rapid trapping of TCPO by intracellular glutathione and/or nucleophiles would explain this lack of effect. These results are not in agreement with those of other studies, which showed an increase in the skin-tumor-initiating ability of BP following TCPO application. (31 refs)

79-1331 Mutagenicity Testing of Some Drug and Cosmetic Dye Lakes with the Salmonella/Mammalian Microsome Assay. (Eng) Brown, J. P. (Dynapol, 1454 Page Mill Road, Palo Alto, CA, 94304); Dietrich, P. S.; Bakner, C. M. *Mutat Res* 66(2): 181-185; 1979.

Ten commonly used coloring agents were tested in the *Salmonella typhimurium*/rat liver microsome mutagenicity assay. The colorants were mostly dye-alumina complexes or insoluble salts from which the dyes were solubilized prior to mutagenicity testing. Each agent was tested with all five basic tester strains (TA1535, TA100, TA1537, TA1538, and TA98), with and without microsomal activation. Three of the agents, D&C Red No. 19, D&C Red No. 36, and D&C Orange No. 17 were mutagenic. Thin-layer chromatographic analysis indicated that Orange No. 17 and Red No. 36 were pure. Red No. 19 (Rhodamine B) contained at least one impurity, which further testing indicated was probably the cause of its mutagenic activity. Each of the agents found to be mutagenic or to contain mutagenic impurities is currently used in drugs and cosmetics. (5 refs)

79-1332 Further Study of the Genetic Toxicity of Gentian Violet. (Eng) Au, W. (Dept. Biology, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Butler, M. A.; Bloom, S. E.; Matney, T. S. *Mutat Res* 66(2): 103-112; 1979.

The mutagenicity of gentian violet (GV) was studied in the *Salmonella typhimurium* and *Escherichia coli* assays and in cytogenetic assays [Chinese hamster ovary (CHO) cells in vitro in the presence of rat liver microsomal (S9) fractions, chicken embryos, and mouse bone marrow cells in vivo]. GV

in the absence of S9 fraction, was bactericidal in the *Salmonella* assay at doses $\geq 10 \mu\text{g}$. It was not toxic in the presence of the S9 fraction. In the *E. coli* assay GV was mutagenic without activation, causing repairable DNA damage. Its activity was reduced, but not eliminated, by the S9 fraction. GV was not clastogenic in chick embryos or mouse bone marrow cells, and it failed to induce sister-chromatid exchanges. However, it was highly toxic to growing chick embryos at doses of 20, 100, 1,000, and 2,000 μg and depressed bone marrow mitotic activity after prolonged treatment. Chromosome damage induced in CHO cells by 5 $\mu\text{g}/\text{ml}$ GV was reduced to control levels by the S9 fraction. In cells treated with 10 $\mu\text{g}/\text{ml}$ GV, a proportional increase in the microsome fraction was required to reduce the induction of chromosome damage. At 20 $\mu\text{g}/\text{ml}$, chromosomes were severely damaged even in the presence of the S9 fraction. These results suggest that GV can be inactivated by the liver detoxification system. However, it is potentially hazardous to cells that are exposed to the dye directly. (15 refs)

79-1333 Human Metabolism of Caffeine (Meeting Abstract). (Eng) Callahan, M. M. (Arthur D. Little, Inc., Cambridge, MA, 02140); Robertson, R. S.; Lavin, M. J.; Yesair, D. W. *Fed Proc* 38(3, part 1): 584; 1979. (no refs)

79-1334 Comparative Effects of Sterculic and Malvalic Acids on the Hepatic Cytochrome P-450 System and Tumor Induction in Rainbow Trout (Meeting Abstract). (Eng) Bailey, M. L. (Dept. Food Science and Technology, Oregon State Univ., Corvallis, OR, 97331); Nixon, J. E.; Hendricks, J. D.; Pawlowski, N. E.; Loveland, P. M.; Sinnhuber, R. O. *Fed Proc* 38(3, part 1): 394; 1979. (1 ref)

79-1335 Long-Term Toxicity Study of Sorbitan Monostearate (Span 60) in Mice. (Eng) Hendy, R. J. (British Industrial Biological Res. Assoc., Woodmansterne Road, Carshalton, Surrey SM5 4DS, England); Butterworth, K. R.; Gaunt, I. F.; Kiss, I. S.; Grasso, P. *Food Cosmet Toxicol* 16(6): 527-534; 1978.

The effects of the food-grade emulsifier sorbitan monostearate (Span 60, 0%-4% of diet for 80 wk) on male and female TO mice were studied. Span 60 had no effects on condition or behavior. Males given 4% Span 60 had a higher total RBC count at 80 wk than untreated males, and total WBC counts were lower in females given 4% Span 60 than in untreated females. At autopsy, the body wts of males given 0.5% and 4% Span 60 were significantly lower than those of untreated males, and both males and females given 4% Span 60 showed enlargement of the kidneys and a higher incidence of nephrosis compared with controls. Other organ-wt changes appeared unlikely to be related directly to treatment. Most of the tumors observed during the study occurred with comparable frequency in the treated and control animals or more frequently in the controls. The no-untoward-effect level of

Span 60 in this study was 2.0% of the diet, or approx 2,600 mg/kg/day. (33 refs)

79-1336 Characterization of Microbial Metabolites of Lithocholic and Sulfolithocholic Acids by High Performance Liquid Chromatography (Meeting Abstract). (Eng) Kelsey, M. I. (NCI, Frederick Cancer Res. Center, Frederick, MD, 21501); Hwang, K. K.; Huang, S. S.; Pontzer, N. J.; Shaikh, B. *Fed Proc* 38(3, part 1): 510; 1979. (no refs)

79-1338 Toxicity of Patulin and Its Interaction with Penicillic Acid (Meeting Abstract). (Eng) Reddy, C. S. (Dept. Pharmacology & Toxicology, Univ. Mississippi Medical Center, Jackson, MS, 39216); Chan, P. K.; Hayes, A. W.; Williams, W. L.; Ciegler, A. *Fed Proc* 38(3, part 1): 679; 1979. (no refs)

79-1339 Mycotoxins in Foodstuffs. XII. The Influence of the Water Activity (a_w) of Cakes on the Growth of Moulds and the Formation of Mycotoxins. (Eng) Reiss, J. (Mikrobiologisches Laboratorium, Grahamhaus Stadt K.G., D-6550 Bad Kreuznach, W. Germany). *Z Lebensm Unters Forsch* 167(6): 419-422; 1978.

The influence of the water activity (WA: ie, the amount of free water directly available to microorganisms) of cakes (made of wheat flour, sugar, eggs, fat, and water) on the development and mycotoxin production of *Aspergillus flavus* (aflatoxins), *A. versicolor* (sterigmatocystin), *A. ochraceus* (ochratoxin A), *Penicillium chrysogenum* (citrinin), and *P. expansum* (patulin) was studied. All fungi showed max growth at the highest WA tested (0.92) and no ability to form visible colonies within 20 days at the lowest WA (0.82). In general, the highest yields of mycotoxins were formed at the highest WA values, although *P. chrysogenum* was unable to form citrinin at any WA. With the exception of sterigmatocystin, however, the yields of mycotoxins were not considerably influenced by the WA. In cakes with a WA of 0.92, the WA decreased after 10 days of incubation (water requirement during germination and initial growth) and then increased to values mostly above the initial levels after 20 days (initiation of secondary metabolism). (19 refs)

79-1340 Polarographic Study of Aflatoxins B₁, B₂, G₁, and G₂: Application of Differential-Pulse Polarography to the Determination of Aflatoxin B₁ in Various Foodstuffs. (Eng) Smyth, M. R. (Dept. Microbiology,

Colorado State Univ., Fort Collins, CO, 80523); Lawellin, D. W.; Osteryoung, J. G. *Analyst* 104(1234): 73-78; 1979.

Studies in which differential-pulse polarography was applied to the determination of aflatoxin B₁ in a variety of food products showed good agreement between the results of this method and those obtained by visual comparison of the fluorescence exhibited by the aflatoxin following thin-layer chromatographic separation. Electroactive interferences co-extracted from foods containing high amounts of lipids were removed by separation on a Sephadex LH-20 column. (9 refs)

79-1341 In Vivo Covalent Binding of Aflatoxin B₁(AFB₁) to DNA by Rats and Mice as a Function of Dose Size (Meeting Abstract). (Eng) Hayes, J. R. (Div. Nutritional Sciences, Cornell Univ., Ithaca, NY, 14853); Campbell, T. C. *Fed Proc* 38(3, part 1): 534; 1979. (no refs)

79-1342 Mutagenicity of Aflatoxin B₁, Activated by S-9 Fractions of Human, Rat, Mouse, Rabbit, and Monkey Liver, Towards *S. typhimurium* TA 98. (Eng) Norpoth, K. (Institut für Staublungenforschung und Arbeitsmedizin, Westfälischen Wilhelms-Universität Münster, D-4400 Münster, W. Germany); Grossmeier, R.; Bosenberg, H.; Themann, H.; Fleischer, M. *Int Arch Occup Environ Health* 42(3/4): 333-339; 1979.

The ability of human liver preparations to activate aflatoxin B₁ (AFB₁) to a mutagen was compared with that of liver preparations from male AF-Wistar rats, NMRI mice, male white New Zealand rabbits, and female Green monkeys using the *Salmonella*/microsome assay and *S. typhimurium* TA98 as the tester strain. Equal liver protein concentrations (1.2 mg/plate) were used to determine the number of his⁺ revertants induced per nanomole of AFB₁ (0.2-0.624 µg/plate). For the rat, rabbit, mouse, monkey, and human preparations, these values were 573, 480, 269, 233, and 36, respectively. With regard to the prediction of human susceptibility from this data, it is unlikely that a low capacity to activate AFB₁ by human liver measured in vitro could be reversed in vivo. It is emphasized, however, that it is impossible to predict in vivo susceptibility from in vitro mutagenicity results precisely. (37 refs)

79-1343 Effect of Phenobarbital and Diethyl Maleate Pretreatment on Covalent Binding of ³H-AFB₁ to Hepatic Macromolecules (Meeting Abstract). (Eng) Allen-Hoffmann, B. L. (Div. Nutritional Sciences, Cornell Univ., Ithaca, NY, 14853); Campbell, T. C. *Fed Proc* 38(3, part 1): 865; 1979. (no refs)

79-1345 Metabolism of Aflatoxin B₁ and Identification of the Major Aflatoxin B₁-DNA Adducts Formed in Cultured Human Bronchus and Colon. (Eng) Autrup, H. (Human Tissue Studies Section, Lab. Experimental Pathology, NCI, Bethesda, MD, 20014); Essigmann, J. M.; Croy, R. G.; Trump, B. F.; Wogan, G. N.; Harris, C. C. *Cancer Res* 39(3): 694-698; 1979.

Studies showing that aflatoxin B₁ (AFB₁) can be activated by cultured human tissues and that the major adduct formed between DNA and AFB₁ is chromatographically identical to the adduct formed in rat liver (an organ susceptible to AFB₁ carcinogenesis) are reported. AFB₁ and benzo(a)pyrene (BP) were activated by both cultured human bronchus and human colon, as measured by binding to cellular DNA and protein. The binding of AFB₁ to DNA was dose-dependent, and the level of binding was higher in cultured human bronchus than it was in the colon. When compared to AFB₁, the binding level of BP to both bronchial and colonic DNA was generally higher. The major adducts formed in both tissues by the interaction of AFB₁ and DNA were chromatographically identical to 2,3-dihydro-2-(N⁷-guanyl)-3-hydroxyaflatoxin B₁ (structure I), with the guanyl group and hydroxy group in the trans-position, and an adduct that has been tentatively identified by other investigators as 2,3-dihydro-2-(N³-formyl-2',5',6'-triamino-4'-oxo-N⁵-pyrimidyl)-3-hydroxyaflatoxin B₁ (Structure II). Seventy percent of the radioactivity associated with bronchial DNA was found in these two peaks, and the ratio of radioactivity between the peaks was nearly 1. In colonic DNA, the ratio between structures I and II was approx 2. These observations add AFB₁ to the list of chemical procarcinogens metabolized by cultured human tissues, in which the carcinogen-DNA adducts are similar to the adducts formed in animal tissue susceptible to the carcinogenicity of AFB₁. 79-1346 Transplacental Action of Sodium Nitrite on Embryonic Cells of Syrian Golden Hamster. (Eng) Inui, N. (Section Cell Biology and Cytogenetics, Biological Res. Center, Japan Tobacco and Salt Public Corporation, Hatano, Kanagawa 257, Japan); Nishi, Y.; Taketomi, M.; Mori, M. *Mutat Res* 66(2): 149-158; 1979.

In utero NaNO₂ treatment (125, 250, or 500 mg/kg to pregnant hamsters by stomach tube on gestation day 11 or 12) produced a marked dose-dependent induction of 8-azaguanine- and ouabain-resistant mutations in Syrian golden hamster embryo cells. Cultured embryonic fibroblasts in the resting state also showed a marked dose-dependent increase in micronucleus formation but no increase in chromosome aberrations. The treatment also produced morphological and neoplastic transformation of the cells. (25 refs)

79-1347 Mutagenicity of Alkaloids in the *Salmonella*/Microsome System. (Eng) Wehner, F. C. (Natl. Res. Inst. Nutritional Diseases, South African Medical Res.

Council, 7505 Tygerberg, South Africa); Thiel, P. G.; Van Rensburg, S. J. *Mutat Res* 66(2): 187-190; 1979.

Evidence that some alkaloids are mutagenic in the *Salmonella*/mammalian microsome test is presented. In the presence of a liver microsome fraction, cycasin was mutagenic for strain TA1535, harmine HCl for TA1537, and retrorsine for TA1535 and TA1537; optimal concentrations were 2.5, 500, and 0.25 $\mu\text{g}/\text{plate}$, respectively. The other alkaloids tested (harmaline, harmame, and macrozamin) were not mutagenic. A base-pair-substituting mutagenic action by cycasin and a frameshift mechanism by harmine are indicated; retrorsine apparently possesses both. *Salmonella* strains containing R-factor plasmids were not reverted by the alkaloids. (15 refs)

- 79-1348 The Multiple Forms and Kinetic Properties of the N-Acetyl- β -D-hexosaminidases from Colonic Tumours and Mucosa of Rats Treated with 1,2-Dimethylhydrazine.** (Eng) Mian, N. (Dept. Experimental Pathology, Univ. Leeds, Leeds LS2 9LS, England); Herries, D. G.; Cowen, D. M.; Batte, E. A. *Biochem J* 177(1): 319-330; 1979.

N-Acetyl- β -D-hexosaminidase (AHA) activities in the colonic tumors and colonic mucosa of 1,2-dimethylhydrazine-treated male Wistar rats were compared. Mucosa contained two forms of AHA, A and B, as well as a third intermediate form. The tumors contained only A and B activities. Each form possessed both N-acetylglucosaminidase and N-acetylgalactosaminidase activities, and these activities could not be separated by a variety of techniques. The mucosa and tumor forms did not differ in terms of inactivation by AgNO_3 or HgCl_2 , inactivation by thimerosal, or response to neuraminidase. However, the K_m of the tumor form B enzyme was significantly lower than that for the mucosa form B. In addition, the tumor form B was significantly more strongly inhibited by monosaccharides, it was slightly more resistant to inactivation by p-hydroxymercuribenzoate, it was protected from inactivation by lower concentrations of glutathione of L-cysteine, and it was more resistant to thermal inactivation than the mucosa form B. The different forms of the AHA's were not interconvertible. The data support the belief that each enzyme form contains glucosaminidase and galactosaminidase activities at separate active sites. - 79-1349 N,N-Dimethylformamide-induced Alteration of Cell Culture Characteristics and Loss of Tumorigenicity in Cultured Human Colon Carcinoma Cells.** (Eng) Dexter, D. L. (Dept. Medicine, Roger Williams General Hosp., 825 Chalkstone Ave., Providence, RI, 02908); Barbosa, J. A.; Calabresi, P. *Cancer Res* 39(3): 1020-1025; 1979.

A study was made of the effects of the polar solvent N,N-dimethylformamide (DMF: 0.8%) on cultures of human carcinoma cell lines DLD-1 and HCT-15 plus two sublines isolated from DLD-1 cells (clones A and D), and the results were compared with observations of untreated cells. There was a 4- to 5-day lag time before morphological

changes in treated cultures were induced completely. Colonies of all four cell types became less circular and more leaf-like at the edges and the cells became less refractile under the light microscope. Doubling times were increased significantly (by a factor of 2-3), saturation densities were reduced, and the ability to grow in soft agar was lost completely (vs a clonogenicity of up to 77% for untreated cells). Growth in the presence of DMF also markedly reduced the tumorigenicity of the cells. Ten of 10 nude mice that received an sc inoculum of 1×10^6 untreated cells developed tumors histologically similar to colonic adenocarcinomas in 10-14 days, but 9/10 nude mice inoculated with 1×10^6 treated cells have shown no sign of tumor 3-6 mo postinjection. Removal of DMF from the culture medium was accompanied within 4-7 days by the reappearance of tumorigenicity and the original cell culture characteristics. Apparently, DMF can reversibly effect the reversion of cultured human colon carcinoma cells to less malignant cell types. (31 refs)

- 79-1350 para-Nitrophenol Uridine Diphosphate Glucuronic Acid Transferase in Microsomes from Livers of Rats Fed Hepatocarcinogens (Meeting Abstract).** (Eng) Walston, K. K. (Oklahoma Medical Res. Foundation, Ardmore and Oklahoma City, OK, 73116); Kizer, D. E.; Griffin, M. J. *Fed Proc* 38(3, part 1): 654; 1979. (no refs)

- 79-1351 Phenoxyacids as Inhibitors of Testicular DNA Synthesis in Male Mice.** (Eng) Seiler, J. P. (Swiss Federal Res. Station, CH-8820 Wädenswil, Switzerland). *Bull Environ Contam Toxicol* 21(1/2): 89-92; 1979.

The abilities of five phenoxyacids to inhibit testicular DNA synthesis in male mice were studied. 2,4-Dichlorophenoxyacetic acid (2,4-D: 200 mg/kg, po), 2,4,5-trichlorophenoxyacetic acid (2,4,5-T: 200 mg/kg, po), 2,4,5-T ester (200 or 400 mg/kg, po), 2-methyl-4-chlorophenoxyacetic acid (MCPA: 200 mg/kg, po), and 2-methyl-4-chlorophenoxypropionic acid (200 mg/kg, po) significantly depressed the uptake of labeled thymidine by testicular DNA. 2,4-Dichlorophenoxypropionic acid (200 mg/kg, po) did not significantly alter thymidine uptake, nor did 2,4,5-T ester at 50 or 100 mg/kg. The mutagenic activity of three of the compounds was previously reported to decrease in the order $\text{MCPA} > 2,4,5\text{-T} > 2,4\text{-D}$; their ability to inhibit testicular thymidine uptake decreased in the same order. (15 refs)

- 79-1352 Activation of 2-Acetylaminofluorene in the Nuclei of Rat Liver.** (Eng) Kawajiri, K. (Biochemistry Div., Saitama Cancer Center Res. Inst., Ina-machi, Kitaadachi-gun, Saitama-ken 362, Japan); Yonekawa, H.; Hara, E.; Tagashira, Y. *Cancer Res* 39(3): 1089-1093; 1979.

The role of the nuclear monooxygenase (NMO) system in the activation of 2-acetylaminofluorene (AAF), a potent hepatocarcinogen, in the nuclei of rat liver cells was investigated using an antibody against microsomal NADPH-cytochrome

c reductase. The relationship between microsomes (MS) and nuclei in the binding of AAF to DNA was also investigated. AAF bound to DNA when incubated with nuclei isolated from Sprague-Dawley rat livers. No binding occurred in the absence of NADPH, which suggests that binding was dependent on NMO. Binding was increased 17-fold by pretreatment of rats with 3-methylcholanthrene (3-MC: 10 mg/kg ip 24 hr before experiments) and inhibited by preincubation of nuclei with the antibody. Binding of AAF to DNA in untreated nuclei was increased by the addition of a small amount of MS (up to a nuclei: MS protein ratio of 0.3), but it gradually decreased upon the addition of higher amounts of MS. The increase in binding was fivefold greater in the presence of 3-MC-treated MS than in the presence of untreated MS. It was inhibited by preincubation of the MS with the antibody, indicating that AAF is activated by a microsomal monooxygenase system and that metabolically activated AAF reaches the nuclei from the endoplasmic reticulum. Addition of MS to 3-MC-treated nuclei decreased the binding of AAF to DNA. Addition of MS from untreated rats resulted in a greater decrease than MS from 3-MC-treated rats. These phenomena can be explained by changes in the influx and efflux of AAF activated in the nuclei and MS across the nuclear membrane. It is suggested that intracellular activation of AAF occurs not only in the endoplasmic reticulum but also in the nuclear envelope. (29 refs)

79-1353 Responsiveness of the Adrenergic Receptor in Parenchymal Cells Isolated from Livers of Rats Fed 2-Acetylaminofluorene (AAF) (Meeting Abstract). (Eng) Hornbrook, K. R. (Univ. Oklahoma Coll. Medicine, Oklahoma City, OK, 73190). *Fed Proc* 38(3, part 1): 540; 1979. (1 ref)

79-1354 The Effect of Time on the Incidence of Carcinomas Obtained by the Implantation of Paraffin Wax Pellets into Mouse Bladder. (Eng) Jull, J. W. (Cancer Res. Centre, Univ. British Columbia, Vancouver, British Columbia, Canada). *Cancer Lett* 6(1): 21-25; 1979.

The effects of paraffin wax pellets with and without added chemicals on the bladder epithelium of 3-mo-old B6AF1/J-type female F1 hybrid mice were studied over a 2-yr period. The pellets were implanted surgically into the mouse bladder lumen. The animals were killed after 40-50, 70-80, and 100-110 wk and examined for proliferative changes in the bladder. In the mice implanted with Leeds paraffin wax pellets, 7/66, 15/56, and 21/39 developed carcinomas at 40-50, 70-80, and 100-110 wk, respectively. In the mice implanted with Vancouver paraffin wax pellets, 0/36 and 9/27 developed carcinomas at 40-50 and 70-80 wk, respectively. In animals implanted with 1-phenylazo-2-naphthol-containing pellets, 20/60, 22/36, and 23/26 developed carcinomas at 40-50, 70-80, and 100-110 wk, respectively. Each of these tumor incidences was statistically significant compared with those in mice in which paraffin pellets alone had been implanted for equivalent periods. Pellets containing

N-2-fluorenylacetamide or its metabolites (1-hydroxy-N-2-fluorenylacetamide, 3-hydroxy-N-2-fluorenylacetamide, or N-2-fluorenylacetohydroxamic acid) gave very similar incidences of carcinomas whether or not they were carcinogenic by po or parenteral administration. These results indicate that the incidence of carcinomas increases with time, and they raise questions about the relative importance of the pellet and the chemical within it in the induction of bladder tumors. 79-1355 DNA-Protein Cross-linking by Chemical Carcinogens in Mammalian Cells. (Eng) Fornace, A. J. (Dept. Pathology, Peter Bent Brigham Hosp., Boston, MA); Little, J. B. *Cancer Res* 39(3): 704-710; 1979.

The induction of DNA cross-linking in human CRL 1220 and mouse C3H/10T1/2 fibroblasts by various carcinogens was investigated by alkaline elution. A dose-dependent increase in DNA cross-linking was seen following exposure of human fibroblasts to N-acetoxy-2-acetylaminofluorene (AAAF) and following exposure of mouse embryo cells to 7,12-dimethylbenz(a)anthracene. No cross-link effect was seen following treatment with N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), benz(a)anthracene, benz(a)anthracene-5,6-dihydroepoxide, or metabolic inhibitors (sodium arsenite, potassium cyanide, and cycloheximide). The cross-linking appeared to be DNA-protein in nature, since proteinase treatment removed the effect. DNA single-strand breaks were also induced by several of these agents. In the case of AAAF and MNNG, approx 70%-90% of these breaks were rejoined after an 18-hr incubation in fresh medium, whereas repair of the cross-links induced by AAAF was slight at this time. (34 refs)

79-1356 Another Approach to In Vivo Estimation of Genetic Damage in Humans. (Eng) Pero, R. W. (Wallenberg Lab., Nucleic Acid Biochemistry, Univ. Lund, Fack 7031, S-220 07 Lund 7, Sweden); Mitelman, F. *Proc Natl Acad Sci USA* 76(1): 462-463; 1979.

Lymphocytes from 28 apparently healthy persons (25 men and 3 women, aged 22-66 yr) were analyzed simultaneously for (1) the level of in vivo chromosome aberrations after 72 hr of phytohemagglutinin stimulation, and (2) the induction of unscheduled DNA synthesis (UDS) after a 1-hr exposure to 10 μ M N-acetoxy-2-acetylaminofluorene (NA-AAF). A highly significant positive linear correlation existed between the two variables; the interindividual variations in NA-AAF-induced UDS paralleled the actual in vivo levels of chromosome damage. It is suggested that measurement of NA-AAF-induced UDS may be a rapid useful supplement in human genetic risk assessment. (18 refs)

79-1357 Carcinogenic Effect of N-Bis(2-hydroxypropyl)nitrosamine by a Single Administration in Rats. (Eng) Konishi, Y. (Dept. Oncological Pathology, Can-

cer Center, Nara Medical Univ., 840 Shijo-cho, Kashihara, Nara 634, Japan); Ikeda, T.; Yoshimura, H.; Kawabata, A.; Mikami, R. *Cancer Lett* 6(2): 115-119; 1979.

The carcinogenic effect of a single ip injection of 3 or 4 g/kg of N-bis(2-hydroxypropyl)nitrosamine (BHP) was studied in 7-wk-old male Wistar rats. Lung tumors (adenomas and adenocarcinomas) were seen in 100% of the rats in both treatment groups. Neoplasms were also induced in the thyroid (adenomas and adenocarcinomas) of 4/11 and 4/12 rats receiving 3 and 4 g/kg BHP, respectively, in the kidney of 1/12 rats receiving 4 g/kg BHP, and in the sigmoid colon of 1/11 rats receiving 3 g/kg BHP. No tumors were detected in control rats after 52 wk and no pancreatic neoplasms were detected. In contrast to the high incidence of bronchogenic adenomas and adenocarcinomas produced in this study, squamous cell carcinomas and adenosquamous cell carcinomas were the major lung tumor types that developed after po BHP administration. Thus, a relationship appears to exist between the route of BHP administration and the morphology of the induced lung neoplasms. (10 refs)

79-1358 Induction of Rat Lung Carcinoma by a Single Injection of N-Bis(2-hydroxypropyl)nitrosamine. (Eng) Konishi, Y. (Dept. Oncological Pathology, Nara Medical Univ., 840 Shijo-cho, Kashihara, Nara-ken 634, Japan); Ikeda, T.; Kawabata, A.; Yoshimura, H.; Mikami, R. *Gann* 69(6): 855-856; 1978.

The carcinogenicity of N-bis(2-hydroxypropyl)nitrosamine (DHPN, 3 or 4 g/kg given as a single ip injection) in 7-wk-old male Wistar rats was determined. All 23 rats sacrificed 52 wk after treatment had developed lung adenomas, and lung adenocarcinomas were found in 9/11 rats in Group 2 (3 g/kg) and 9/12 rats in Group 3 (4 g/kg). Group 1 was untreated (controls). Adenomas of the thyroid were detected in 2/11 Group 2 rats and in 3/12 Group 3 rats; thyroid adenocarcinomas were detected in 2 Group 2 rats and 1 Group 3 rat; an adenocarcinoma of the sigmoid colon was found in 1 Group 2 rat; and a renal cell carcinoma was found in 1 Group 3 rat. No tumors were found in Group 1 rats. The data demonstrate the carcinogenicity of ip DHPN and indicate that the DHPN-induced rat lung carcinoma is a useful model for studying the initiation and promotion of carcinogenesis. (9 refs)

79-1359 Mutagenicity of Some N- and O-Acyl Derivatives of N-Hydroxy-2-aminofluorene in V79 Chinese Hamster Cells. (Eng) Kuroki, T. (Dept. Cancer Cell Res., Inst. Medical Science, Univ. Tokyo, Shirokanedai, Minato-ku, Tokyo 108, Japan); Bartsch, H. *Cancer Lett* 6(2): 67-72; 1979.

The mutagenicity of four N- and O-acyl derivatives of N-hydroxy-2-aminofluorene (acyl: acetyl or myristoyl residue) was examined in V79 Chinese hamster cells in the absence of a metabolic activation system.

N-Myristoyloxy-N-acetyl-2-aminofluorene (5-50 μ M) was toxic and weakly mutagenic, inducing 8-azaguanine-resistant mutants in the cells in a concentration-dependent fashion. N-Acetoxy-N-myristoyl-2-aminofluorene (5-50 μ M) and N-myristoyloxy-N-myristoyl-2-aminofluorene (6.3-25.0 μ M) were neither cytotoxic nor mutagenic. Under the same conditions, N-acetoxy-N-acetyl-2-aminofluorene (4-16 μ M) was highly toxic and mutagenic. Neither of the two N-myristoyloxy derivatives was mutagenic in *Salmonella typhimurium*. These esters have been reported to produce local tumors at the site of their injection in rats, to be electrophilic toward methionine, and to induce unscheduled DNA synthesis in cultured human fibroblasts. However, the fact that some of the esters were not mutagenic in *S. typhimurium* or in V79 Chinese hamster cells emphasizes the need for multiple short-term tests in predicting the potential carcinogenic activity of chemicals. (10 refs)

79-1360 Validation and Characterization of the L5178Y/TK+/- Mouse Lymphoma Mutagen Assay System. (Eng) Clive, D. (Genetic Toxicology Lab., Burroughs Wellcome Co., Research Triangle Park, NC, 27709); Johnson, K. O.; Spector, J. F.; Batson, A. G.; Brown, M. M. *Mutat Res* 59(1): 61-108; 1979.

A specific-locus mutagenicity assay using L5178Y mouse lymphoma cells rendered heterozygous at the normally diploid thymidine kinase (TK) locus and supplemented with an exogenous in vitro metabolic activation system was validated. Validation took the form of dose-response data for 43 chemicals, including mutagens and carcinogens of varying potencies and several agents designed for human exposure. Mutagenicity and cytotoxicity in the presence or absence of noninduced and/or Aroclor-induced rat liver S-9 mix were compared for most of the chemicals. Twenty-five chemicals for which usable carcinogenicity data exist were used to construct an approx linear relationship between oncogenic potency in vivo and mutagenic potency in this system in vitro; linearity between these two endpoints extended over a > 100,000-fold range in potencies. Natulan, sodium saccharin, 1,1-dichloro-2,2-bis(p-chlorophenyl)ethylene dimethylnitrosamine, diethylnitrosamine, and diethylstilbestrol, which are either negative or difficult to detect in the standard Ames assay, were mutagenic in this mammalian cell system. Characterization of the TK-/- mutants suggested that two mutagenic mechanisms contribute to their final yield. Large colony TK-/- mutants probably represent point or gene mutations affecting the TK locus. In addition, a class of small colony TK-/- mutants was described and characterized as being heritably growth-deficient; this and other properties suggest that these small colony TK-/- mutants originate by a heritable and viable chromosomal aberration. Most carcinogens and mutagens tested produced both classes of TK-/- mutants in this system; the relative proportions of small and large colony mutants were both mutagen- and dose-dependent. Comparative studies at the rapidly expressing TK locus and the slowly expressing hypoxanthine-guanine phosphoribosyltransferase (HGPRT) locus in these cells showed

that several carcinogens detected at the TK locus are non- or very weakly mutagenic at the HGPRT locus. This is consistent with the induction of slow-growing specific locus mutants by a chromosomal mechanism and their subsequent dilution during this long expression time. (47 refs)

79-1361 The Kinetics of Dimethylamino Radical Reactions in Simulated Atmospheres: The Formation of Dimethylnitrosamine and Dimethylnitramine (Meeting Abstract). (Eng) Lindley, C. R. (Ohio State Univ., Columbus, OH, 43210). *Diss Abstr Int B* 39(8): 3857; 1979. (no refs)

79-1362 Effects of Thiamine Deficiency on the Metabolism and Toxicity of Dimethylnitrosamine (Meeting Abstract). (Eng) Ruchirawat, M. (Mahidol Univ., Bangkok, Thailand); Mahathanatrakul, W.; Sinrathanant, Y.; Kittikool, D. *Fed Proc* 38(3, part 1): 869; 1979. (no refs)

79-1363 Oxidative Metabolism of Dimethylnitrosamine: Correlation with Toxicity. (Eng) Ruchirawat, M. (Dept. Pharmacology, Faculty Science, Mahidol Univ., Rama VI Road, Bangkok 4, Thailand); Shank, R. C. *J Toxicol Environ Health* 4(1): 161-172; 1978.

A study of the relationship between oxidative metabolism and acute dimethylnitrosamine (DMN) toxicity demonstrated that max DMN metabolism in the neonatal rat liver occurs between days 5 and 21 of age and in the kidney between days 15 and 21. Evidence suggesting that more than one enzyme may be responsible for DMN oxidation to CO₂ is presented. Rats were most sensitive to DMN toxicity at 5 days of age, but DMN conversion to CO₂ was not well-correlated with toxicity. (23 refs)

79-1364 Mechanism of Metabolic Activation of Dimethylnitrosamine (DMN) (Meeting Abstract). (Eng) Woo, Y. T. (USPHS Res. Lab., Tulane Medical Center, New Orleans, LA, 70118); Lai, D. Y.; Argus, M. F.; Arcos, J. C. *Fed Proc* 38(3, part 1): 536; 1979. (no refs)

79-1365 A Synergistic Effect of Nitrosodimethylamine on Sterigmatocystin Carcinogenesis in Rats. (Eng) Terao, K. (Res. Inst. Chemobiodynamics, Chiba Univ., 280 Chiba, Inohana 1-8-1, Japan); Aikawa, T.; Kera, K. *Food Cosmet Toxicol* 16(6): 591-596; 1978.

Male Wistar rats (4 wk old) were fed diets containing 10 ppm sterigmatocystin (STG), 10 ppm STG + 1 ppm nitrosodimethylamine (NDMA), 1 ppm STG + 10 ppm NDMA, or 10 ppm NDMA for 54 wk. No pathological changes were detected by light microscopy at 5 wk, but electron microscopy showed a marked proliferation of the smooth endoplasmic reticulum and an accumulation of inter- and perichromatin granules in the hepatocytes. Hepatic carcinomas developed

in 75% of the rats fed 10 ppm STG + 1 ppm NDMA and in 53% of those fed 10 ppm STG alone. The hepatic carcinomas were detected at 57 wk in the former group and at 60 wk in the latter. There were no hepatic carcinomas in rats fed 10 ppm NDMA alone. About 50% of the hepatic carcinomas induced by STG or STG + NDMA showed a tubular arrangement of tumor cells. Ultrastructurally, a mixture of the characteristic organelles of hepatocytes and ductular cells were frequently found in the same cells. After 54 wk, Leydig-cell tumors were detected in 47% of animals fed 10 ppm NDMA, 45% of animals fed 1 ppm STG + 10 ppm NDMA, and 15% of animals fed 10 ppm STG + 1 ppm NDMA. No metastases were observed. These results demonstrate that a low concentration of NDMA may act synergistically in STG hepatocarcinogenesis, perhaps by inducing carcinogen-activating enzymes. (21 refs)

79-1366 Carcinogen-induced Abnormalities in Rat Liver Cells and Their Modification by Chemical Agents. (Eng) Borenfreund, E. (Lab. Cell Biochemistry, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Higgins, P. J.; Steinglass, M.; Bendich, A. *Cancer Res* 39(3): 800-807; 1979.

The nature of the carcinogen-induced abnormalities in Wistar rat liver cells and the ability of certain chemicals to modify them were studied. Epithelial cells from livers of rats bearing diethylnitrosamine-induced hepatocarcinomas were propagated in vitro and cloned. These cells exhibited acentric nuclei and juxtanuclear cytoplasmic lesions indistinguishable from the Mallory hyaline bodies found in the cirrhotic livers of alcoholics. The hyaline region was comprised of a filamentous aggregate in the cytoplasm that contained components that bound concanavalin A, an interaction that was blocked by α -methylmannopyranoside. This hepatocellular aggregate also bound IgG from the sera of normal rabbits and patients with advanced alcoholic cirrhosis. The IgG fraction of sera from normal goats, rats, or mice did not show such an affinity. The morphological appearance of cells containing this Mallory body-like lesion was altered, in a reversible reaction, to one resembling normal rat liver epithelial cells after incubation with dimethyl sulfoxide or sodium butyrate. Such treatment also caused the cells to lose their acquired ability to localize concanavalin A and IgG in the juxtanuclear region. The presence of the filamentous aggregate may be responsible for the acentric displacement of the nucleus and might be correlated with the ability of the cells to express certain in vitro properties associated with the transformed state. The cytoplasmic lesion may reflect an impairment of microtubular function and polymerization. (57 refs)

79-1367 Pancreatic Ductulitis in Syrian Golden Hamsters Bearing Homologous Transplantable Pancreatic Adenocarcinomas. (Eng) Runge, R. (Epply Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE, 68105); Takahashi, M.; Pour, P. *Cancer Lett* 5(4): 225-229; 1978.

Pancreatic alterations in four Syrian hamsters that had received homologous, nonsyngeneic, transplantable, N-nitrosobis(2-oxopropyl)amine-induced pancreatic adenocarcinomas are reported. In 4/45 tumor bearers, a peculiar form of pancreatitis occurred without preferential involvement of specific pancreatic segments. It consisted of an acute inflammatory infiltrate of varying severity around or within the intralobular ductules and some islets. In some areas, there was a scant infiltration of granulocytes and in others, the ductules were essentially destroyed by a heavy infiltration of polymorphonuclear WBC. Some areas within affected organs showed no inflammation. There was no relationship between the degree or extent of inflammation and the number of tumor passages or actual size of tumors. The small blood vessels accompanying the affected ductules showed no evidence of the acute inflammation sometimes seen in Arthus-type reactions. However, all affected animals had pulmonary metastases, and the implanted tumors and metastases showed some infiltration by acute and chronic inflammatory cells. The data provide evidence that induced pancreatic neoplasms originate from ductules. (10 refs)

- 79-1368 Ductular Origin of Pancreatic Cancer and Its Multiplicity in Man Comparable to Experimentally Induced Tumors. A Preliminary Study.** (Eng) Pour, P. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Salmasi, S. Z.; Runge, R. G. *Cancer Lett* 6(2): 89-97; 1979.

The morphologic alterations of three randomly selected human pancreatic cancers (in men aged 45, 68, and 76) were compared with those found in Syrian hamsters after treatment with N-nitrosobis(2-oxopropyl)amine (BOP). The three human cases exhibited hyperplastic, preneoplastic, and malignant changes that were markedly multicentric and that arose predominantly from ductules, as well as from small ducts. The findings were comparable to those in the hamster model. Proliferation and malignant alterations of the intralobular ductules were commonly seen in both human and experimental tumors. The data are consistent with the concept that cells of the small ducts and, especially, of the ductules represent a potential source of human, as well as experimental, tumors. The small number of human cases studied does not allow generalization, but the marked resemblances in all three randomly selected pancreatic cancer cases were remarkable. (19 refs)

thesda, MD, 20014); Tralka, T. S.; Hanna, C. H.; Kaplan, A. E. *Fed Proc* 38(3, part 1): 579; 1979. (1 ref)

- 79-1371 Sensitive Radioimmunoassay for Detection of O⁶-Ethyldeoxyguanosine in DNA Exposed to the Carcinogen Ethylnitrosourea In Vivo or In Vitro.** (Eng) Muller, R. (Institut für Zellbiologie, Universität Essen, Hufelandstrasse 55, D-4300 Essen 1, W. Germany); Rajewsky, M. F. *Z Naturforsch C* 33(11/12): 897-901; 1978.

A radioimmunoassay was developed for the specific detection of low levels of O⁶-ethyl-2'-deoxyguanosine (EDG), a major premutational product formed in both intracellular DNA and in purified DNA in vitro after exposure to the carcinogen N-ethyl-N-nitrosourea (ENU). Antibodies directed against EDG were obtained by immunizing rabbits with a conjugate of O⁶-ethylguanosine and bovine serum albumin. Using these antibodies and ³H-labeled EDG as tracer in a competitive radioimmunoassay, 0.3 picomole of EDG were sufficient to inhibit tracer-antibody binding by 50% (antibody association constant, 7×10^8 moles⁻¹). All other alkylated DNA components analyzed exhibited considerably lower degrees of inhibition. In a sample of 130 µg of hydrolyzed DNA (equivalent to the DNA level in 2×10^7 diploid cells) EDG could be measured at a molar ratio of EDG/2'-deoxyguanosine of 3×10^{-6} , ie, about 5×10^3 EDG molecules per diploid cell. Two examples are given for the quantitation of EDG in DNA exposed to ENU in vivo or in vitro. These studies indicate the potential of immunological methods for the specific recognition of molecular structures in DNA and for the detection and quantitation of structural alterations of DNA by carcinogenic and mutagenic agents. - 79-1372 Modification of L1210 Cell Nuclear Proteins by 1-Methyl-1-nitrosourea and 1-Methyl-3-nitro-1-nitrosoguanidine.** (Eng) Pinsky, S. D. (Dept. Medicine, Div. Medical Oncology, V. T. Lombardi Cancer Res. Center, Georgetown Univ. Sch. Medicine, Washington, DC, 20007); Tew, K. D.; Smulson, M. E.; Woolley, P. V. *Cancer Res* 39(3): 923-928; 1979.

Modification of the nuclear proteins of L1210 cells in culture by 1-methyl-1-nitrosourea (MNU) and 1-methyl-3-nitro-1-nitrosoguanidine (MNNG) was examined. Preparations of radiolabeled drug were available that permitted examination of carbamylation and alkylation by MNU and of guanidination and alkylation by MNNG. Nuclear proteins were isolated from the cells following 1 hr of incubation at 37 C with 0.038-3.8 mM of ¹⁴C-labeled carcinogens. Separation of the proteins by sodium dodecyl sulfate-polyacrylamide gel electrophoresis and Triton-acetic acid-urea gel electrophoresis yielded comparable results. All histones and many nonhistones were modified. At 0.38 mM, binding ranged from the lowest detectable level of 0.1 picomole (pmol) of [carbonyl-¹⁴C]MNU/nanomole (nmol) of H4 (carbamylation) to 13.1 pmol [methyl-¹⁴C]MNNG/nmol H2A. MNNG was approx 12 times as potent as MNU at that

concentration, and it showed more binding than MNU at all doses for both types of reactions. H1 was more strongly guanidinated than the other histones (11.0 pmol/nmol at 0.38 mM), but H2B and H3 were the major targets of carbamoylation (0.9 and 118 pmol/nmol, respectively, at 0.38 mM). With both drugs, methylation of H1 and H2A was most marked. Generally, there was twice as much binding to acid-soluble nonhistones. The results show that nuclear proteins are modified upon exposure to MNU and MNNG. (30 refs)

- 79-1373 Neoplasms in Rats and Mice Fed Butylurea and Sodium Nitrite Separately and in Combination.** (Eng) Murthy, A. S. (EG&G Mason Res. Inst., Worcester, MA, 01508); Baker, J. R.; Smith, E. R.; Zepp, E. *Int J Cancer* 23(2): 253-259; 1979.

Fischer 344 rats and C57BL/6 mice were fed 0.58% butylurea and/or 0.50% sodium nitrite mixed in the diet for 365 days, followed by 120 days on a stock diet. The number and type of neoplasms were not significantly increased in either species receiving butylurea or sodium nitrite alone. Feeding the two chemicals simultaneously induced neoplasms of the lung, Zymbal's gland, forestomach, intestine, and hemopoietic tissues in rats and malignant lymphomas in mice. Tumor incidence was increased from control values for male and female rats of 60% and 45%, respectively, to 93% and 98%; the increase in male and female mice was from control values of 8% and 18%, respectively, to 90% and 67%. The increased incidence of neoplasms in rats and mice fed butylurea plus sodium nitrite may result from in vivo formation of the carcinogen N-butyl-N-nitrosourea. (37 refs)

- 79-1374 Effects of Iodine Deficiency and High-Fat Diet on N-Nitrosomethylurea-induced Mammary Cancers in Rats.** (Eng) Cave, W. T. (Div. Endocrinology, Dept. Internal Medicine, Univ. Rochester Sch. Medicine and Dentistry, Rochester, NY, 14611); Dunn, J. T.; MacLeod, R. M. *Cancer Res* 39(3): 729-734; 1979.

The effects of dietary iodine and fat on the development of N-nitrosomethylurea (NMU)-induced mammary tumors were studied in female Buffalo, Wistar-Furth, and Fischer rats. NMU (5 mg/100 g) was administered iv to 50-day-old rats, with two subsequent injections given 4 and 8 wk later. The animals were maintained on a standard diet containing 4.63% fat and 1.1 to 1.4 ppm iodine, a special diet (LIHF) containing 11.8% fat and <0.1 ppm iodine, an iodine-supplemented (1.6 ppm) LIHF diet, or an iodine-supplemented, vitamin-deficient LIHF diet. The number of tumors and the tumor mass were larger in the animals given the supplemented or unsupplemented LIHF diet than in those given the standard diet. Enlargement of the kidney, liver, and spleen was evident in the groups with the greatest tumor growth, but there was little evidence of altered pituitary function in these animals. Ovariectomy following the last dose of NMU prevented the accelerated tumor growth in the animals given

the LIHF diets. Ovariectomy also led to a significant depression in thyroid-stimulating hormone (TSH) and prolactin (PRL) production in vitro, and to a less significant decrease in serum PRL. The data indicate that iodine deficiency did not significantly promote NMU carcinogenesis and that estrogens may directly influence TSH synthesis in vivo. (30 refs)

- 79-1375 An Experimental Model for Peripheral Nerve Tumours in Monkeys.** (Eng) Dimant, J. N. (Institute Oncology and Radiology, Ministry of Health of the Uzbekian SSR, Tashkent, USSR); Beniashvili, D. S. *J Med Primatol* 7(5): 324-329; 1978.

Tumor induction was studied in five *Macaca mulatta* monkeys treated with methylnitrosourea (MNU: 15 iv injections of 20 mg/kg over 3 mo) and in seven monkeys treated with MNU + antigen from the homologous tissue of the sciatic nerve from another *Macaca mulatta* monkey (introduced with Freund's complete adjuvant into the interscapular space a total of 6 times starting 2 wk after the second MNU injection). The total dose of MNU ranged from 840 to 1,350. The monkeys were observed for 3 yr. Circumscribed benign neurinomas attached to the trunk of the sciatic nerve were found in 3/7 animals treated with MNU + antigen. The first palpable tumor was found 15 mo after the beginning of the experiment, and all animals with induced neurogenic tumors showed partial distortion of sciatic nerve conduction, as manifested by paresis of the muscles innervated by this nerve. The induced peripheral nerve tumors were similar in pathology, biologic properties, and clinical manifestations to the human tumors. No tumors were found in animals treated with MNU alone. The results suggest that organospecific immunization aids in the initiation and stimulation of MNU-induced neoplasia in the peripheral nervous system. (3 refs)

- 79-1376 Rifampicin as a Spectroscopic Probe of the Mechanism of *E. Coli* RNA Polymerase (Meeting Abstract).** (Eng) Reisbig, R. (Dept. Biochemistry, Colorado State Univ., Fort Collins, CO, 80523); Woody, A. Y.; Woody, R. W. *Biophys J* 25(2, part 2): 221a; 1979. (no refs)

- 79-1378 Carcinogenesis Bioassay of Technical-Grade Piperonyl Butoxide in F344 Rats.** (Eng) Cardy, R. H. (Dept. Pathology, Litton Bionetics, 5516 Nicholson Lane, Kensington, MD, 20795); Renne, R. A.; Warner, J. W.; Cypher, R. L. *J Natl Cancer Inst* 62(3): 569-578; 1979.

The results of a 2-yr carcinogenesis bioassay of the insecticide synergist piperonyl butoxide, α -[2-(2-butoxyethoxy)]-4,5-methylenedioxy-2-propyltoluene, in inbred F344 rats are reported. Doses of 10,000 and 5,000 ppm of the compound were administered continuously in the feed. Although a statistically significant dose-related increase in the incidence of lymphoreticular neoplasia occurred in females, the incidence of this class of neoplasm was higher in control males than in treated males. The finding of statistical significance in one sex is not sufficient evidence of a biologic effect to justify an indictment of carcinogenic action. However, inasmuch as the chief use of this substance is to alter the *in vivo* metabolism of other chemicals, its possible role as a cocarcinogen should be carefully considered in any risk-benefit evaluation aimed at settling policies regarding its uses. (16 refs)

- 79-1379 The Effect of Nitrofurans on Mitosis, Chromosome Breakage and Sister-Chromatid Exchanges in Human Peripheral Lymphocytes.** (Eng) Cohen, M. M. (Dept. Human Genetics, Hadassah Hebrew Univ. Medical Center, Jerusalem, Israel); Sagi, M. *Mutat Res* 59(1): 139-142; 1979.

The effects of two antimicrobial nitrofurans, 3-amino-6-[2-(5-nitro-2-furyl)vinyl]pyridazine (Carofur, CF) and 3-(5-nitrofurylideneamino)-2-oxazolidone (Furazolidone, FZ), on cell division, chromosome breakage, and the induction of sister-chromatid exchanges were studied in cultured human peripheral lymphocytes. Both compounds (0.2, 2.0, and 20.0 $\mu\text{g}/\text{ml}$) produced dose-dependent mitotic suppression, chromosome breakage, and sister-chromatid exchanges; these changes were more pronounced with FZ. Statistically significant differences ($p < 0.001$) in sister-chromatid exchange frequency were noted when controls and treated cells were compared. Differential staining was absent at the highest CF dose, possibly as a result of a long mitotic delay of the sensitive S cells. (22 refs)

- 79-1380 Sterigmatocystin-DNA Interactions: Identification of a Major Adduct Formed after Metabolic Activation In Vitro.** (Eng) Essigmann, J. M. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139); Barker, L. J.; Fowler, K. W.; Francisco, M. A.; Reinhold, V. N.; Wogan, G. N. *Proc Natl Acad Sci USA* 76(1): 179-183; 1979.

The metabolic activation and DNA binding of sterigmatocystin (ST), a potent hepatocarcinogen, were investigated. ST was covalently bound to calf thymus DNA by incubation in the presence of phenobarbital-induced rat liver microsomes. Acid hydrolysis of ST-modified DNA liberated a major guanine-containing adduct, present in DNA at an estimated level of 1 ST residue/100-150 nucleotides. The adduct was isolated by high-pressure liquid chromatography and subjected to structural analysis. Spectral and chemical data identified the adduct as 1,2-dihydro-2-(N'-guanyl)-1-hydroxysterigmatocystin, the guanine and hydroxyl moieties being in a trans

configuration. The structure and stereochemistry of this adduct indicated that the *exo*-ST-1,2-oxide was the metabolite that reacted with DNA, and the quantitative yield of adduct indicated that this metabolite was a major product of the *in vitro* metabolism of ST. (37 refs)

- 79-1381 Carcinogenicity of Di(N-nitroso)-perhydropyrimidine (DNPP) after Intraperitoneal Application to Rats.** (Eng) Bertram, B. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Heidelberg, W. Germany); Habs, M.; Wiessler, M.; Braun, H.; Kretzer, H. *Cancer Lett* 6(1): 57-60; 1979.

The carcinogenicity of di(N-nitroso)perhydropyrimidine (DNPP) was assessed in male Sprague-Dawley rats. The rats received 30 mg/kg (group 1) or 15 mg/kg (Group 2) DNPP ip 1x/wk for life. DNPP treatment significantly reduced the life expectancy in both groups. At 34 wk after the start of treatment, survivors included 13% of Group 1 and 0% of Group 2 vs 93% of controls. The median survival of Groups 1 and 2 was 51 and 156 days, respectively. DNPP induced both benign and malignant tumors of the esophagus (27% incidence in Group 1, 33% in Group 2) and possibly also of the liver (4% incidence in Group 1, 8% in Group 2). No tumors were found in controls. (9 refs)

- 79-1382 Mutation Induction by 5-Fluorodeoxyuridine in Synchronous Chinese Hamster Cells.** (Eng) Aebersold, P. M. (Dept. Molecular Biology, Univ. California, Berkeley, CA, 94720). *Cancer Res* 39(3): 808-810; 1979.

The mutagenicity of 5-fluorodeoxyuridine (FUdR: 0.2 $\mu\text{g}/\text{ml}$) to Chinese hamster ovary cells synchronized by mitotic detachment was studied. In synchronous cultures treated with FUdR (0.2 $\mu\text{g}/\text{ml}$ for 1 hr at various times after mitotic detachment), there was a peak of induced 6-thioguanine (6-TG) resistance about 8 hr after mitotic detachment. FUdR treatment (0.2 $\mu\text{g}/\text{ml}$) of cells synchronized at the G₁-S boundary with hydroxyurea did not significantly affect colony formation or plating efficiency at the time of 6-TG selection. Although 2.0 $\mu\text{g}/\text{ml}$ FUdR reduced colony formation only slightly, the colonies were less than one-half the diameter of untreated colonies and the plating efficiency of cells at the time of 6-TG selection was reduced by 75%. FUdR (0.2 $\mu\text{g}/\text{ml}$) was not significantly mutagenic in asynchronous cells. A total of 24 6-TG-resistant colonies were observed on five plates of synchronized cells treated with FUdR alone, but only 1 6-TG-resistant colony was observed on five plates treated with FUdR + 10^{-4} M thymidine. The data suggest that FUdR treatment leads to mutagenesis at the growing points of DNA replication. (11 refs)

- 79-1383 N⁶(Methylnitroso)adenosine: A Carcinogenic Nitrosamine Derived from a Naturally-occurring Nucleoside.** (Eng) Giner-Sorolla, A. (Walker Lab., Memorial Sloan-Kettering Cancer Center, Rye, NY, 10580);

Greenbaum, J. H.; Last-Barney, K.; Anderson, L. M.; Budinger, J. M. *Cancer Lett* 6(2): 79-82; 1979.

The carcinogenicity of N⁶(methylnitroso)adenosine [M⁶(NO)Ado], the nitrosated derivative of the naturally occurring modified nucleoside N⁶-methyladenosine, was tested in Swiss mice. Pregnant females were injected on days 15, 17, and 19 of gestation; their offspring were injected on days 4, 7, and 10 and then, starting on day 21, 3x/wk for 12 wk (all at 40 mg/kg ip). In the injected mice, 84% of the females and 44% of the males died with thymic lymphomas between 12 and 36 wk of age. Primary lung tumors were found in 71% of these females and in 58% of the males. Liver tumors were found in 33% of the treated male mice at 1 yr of age compared with 17% of the controls; none were found in treated females. The high incidence of tumors in three different tissues following M⁶(NO)Ado treatment strongly suggests direct carcinogenesis, although an increase in spontaneous tumors as a result of indirect effects cannot be ruled out. It is suggested that M⁶(NO)Ado be included in considerations of carcinogenic nitrosamines in food and in the gastrointestinal tract. (9 refs)

79-1384 Biliary Excretion of [¹⁴C]Penicillic Acid by Rats. (Eng) Park, D. L. (Office Health Affairs, Food and Drug Admin., Washington, DC, 20204); Brouwer, E.; Heath, J. L. *J Toxicol Environ Health* 4(1): 9-13; 1978.

A study of the biliary excretion of ¹⁴C-penicillic acid in male rats using straight and recycle cannulation techniques demonstrated that the radioactivity level in bile was five times greater with straight cannulation. Variability of the level of radioactivity was much less with the recycle technique than with straight cannulation. The biological half-retention life for ¹⁴C-penicillic acid in bile was 3.63 hr. (9 refs)

79-1385 Production of Sister Chromatid Exchanges by Various Cancer Chemotherapeutic Agents. (Eng) Banerjee, A. (Div. Hematology-Oncology, Dept. Medicine, Children's Hosp. Los Angeles, Los Angeles, CA, 90027); Benedict, W. F. *Cancer Res* 39(3): 797-799; 1979.

Various cancer chemotherapeutic agents were tested for their ability to produce increases in sister chromatid exchanges (SCE's) in cloned hamster A(T₁)C1-3 cells. The two alkylating agents melphalan and thiotepa [tris(1-aziridinyl)phosphine sulfide] produced significant dose-dependent increases in SCE's, the former at doses as low as 0.005 µg/ml and the latter at doses as low as 0.01 µg/ml. Actinomycin D and bleomycin were significantly less efficient in inducing SCE's. The antimetabolite methotrexate significantly increased SCE's at a concentration of 0.1 µg/ml, whereas 6-mercaptopurine was ineffective even at 1.0 µg/ml. Hycanthone at 1.0 µg/ml and 5-azacytidine at 2.5 µg/ml produced three-fold increases in SCE's. Tilorone did not increase the frequency of SCE's even at 5 µg/ml. Determination of increases in SCE production may be an additional sensitive

method for detecting potential mutagenic and/or oncogenic agents in the environment. (15 refs)

79-1386 Mutagenicity and Mutagenic Specificity of Metronidazole and Niridazole in *Neurospora crassa*. (Eng) Ong, T. (Natl. Inst. Occupational Safety and Health, ALOSH, Morgantown, WV, 26505); Slade, B. *J Toxicol Environ Health* 4(5/6): 815-824; 1978.

Mutagenicity and mutagenic specificity studies of niridazole and metronidazole in the adenine-3 test system of *Neurospora crassa* demonstrated that neither is mutagenic in resting conidia, but that both are mutagenic in the growing vegetative cells. The genetic alterations induced by metronidazole were similar to those induced by several monofunctional alkylating agents. Niridazole induced predominantly base-pair substitution mutations. (27 refs)

79-1387 Mechanism of N-Nitrosopyrrolidine Formation in Bacon. (Eng) Bharucha, K. R. (Canada Packers Ltd., Toronto, Ontario, Canada, M6N 1K4); Cross, C. K.; Rubin, L. J. *J Agric Food Chem* 27(1): 63-69; 1979.

Experiments demonstrate that N-nitrosopyrrolidine in cooked bacon arises by decarboxylation of N-nitrosoproline, which is probably formed by radical nitrosation of free proline in the pork belly. A method for measuring N-nitrosoproline in raw bacon is described. It demonstrated that raw bacon is essentially free of volatile nitrosamines. (37 refs)

79-1388 Malignant Transformation In Vitro by Tryptophan Pyrolysis Products. (Eng) Takayama, S. (Dept. Experimental Pathology, Cancer Inst., 1-37-1, Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Hirakawa, T.; Sugimura, T. *Proc Jpn Acad Ser B* 54(7): 418-422; 1978.

In vitro hamster embryo cells underwent malignant transformation after treatment with tryptophan pyrolysis products and 3-methylcholanthrene. When the cells were inoculated into hamster cheek pouches, small nodules were seen within a week. The tumors consisted of pleomorphic fibroblastic cells, and they appeared to be anaplastic fibrosarcomas. (9 refs)

79-1389 The Effect of L-Tryptophan and Certain Other Amino Acids on Liver Nitrosodimethylamine Demethylase Activity. (Eng) Evarts, R. P. (Carcinogen Metabolism and Toxicology Branch, NCI, Bethesda, MD, 20014); Mostafa, M. H. *Food Cosmet Toxicol* 16(6): 585-589; 1978.

The effect of the amino acids L-tryptophan, L-cysteine, L-methionine, L-tyrosine, and L-glycine on liver nitrosodimethylamine-demethylase (NDMA-demethylase) ac-

tivity was studied in male Wistar rats. Each amino acid was fed at a level of 1% of the diet to weanling rats for 12 days. L-Tryptophan increased liver NDMA-demethylase activity significantly above that of control animals, but L-cysteine had the opposite effect. The other amino acids did not alter enzyme levels. L-tryptophan was effective when it was given to young rats for 6 or 12 days and the animals were killed at the age of 27 or 35 days. When the effect of the duration of tryptophan feeding (3-47 days) and at the age of the animals (21-51 days) were taken into account, a 6-day feeding schedule had the highest activating effect on liver NDMA-demethylase (30% above control values). The highest activation (180%) was obtained when the 6-day period of tryptophan feeding was started at age 27 days and the animals were killed at the age of 33 days. The highest enzyme activities were always associated with a high liver wt:body wt ratio. Other reports have indicated that a low-protein diet protects against toxicity and a high-protein diet against carcinogenicity. The fact that tryptophan and cysteine affect the activity of microsomal enzymes indicates that the amino acid composition of the diet is important in determining the toxicity and carcinogenicity of foreign compounds. (33 refs)

- 79-1390** Microsomal Biphenyl 2-Hydroxylation in the Presence of Some Carcinogenic Alkylaryltriazenes. (Eng) McPherson, F. (Smith Kline and French Labs., Ltd., Welwyn Garden City, Herts, England); Kolar, G. F. *Cancer Lett* 6(1): 33-38; 1979.

A hepatic mixed-function oxygenase system, which gave enhanced biphenyl 2-hydroxylation in the presence of known carcinogens in vitro, was tested as a short-term assay for the detection of dangerous compounds using eight carcinogenic triazenes: 3,3-dimethyl-1-phenyltriazene, 3-methyl-1-phenyltriazene, 1-(4-bromophenyl)-3,3-dimethyltriazene, 1-(2,4,6-tribromophenyl)-3,3-dimethyltriazene, 1-(2,4,6-tribromophenyl)-3-methyltriazene, 1-(4-chlorophenyl)-3,3-dimethyltriazene, 1-(2,4,6-trichlorophenyl)-3,3-dimethyltriazene, and 1-(2,4,6-trichlorophenyl)-3-methyltriazene. The test triazene (0.5 mg in 0.5 ml groundnut oil) was added to hepatic microsomes prepared from adult male Wistar rats, and the mixture was preincubated 10 min in the presence of an NADPH-generating system. Biphenyl was then added, and the incubation was continued for 5 min. 2- and 4-hydroxybiphenyls were extracted and determined fluorimetrically. Preincubation of the test system with 20-methylcholanthrene or with safrole significantly enhanced biphenyl 2-hydroxylation (380% and 193%, respectively, compared with 100% in controls). However, preincubation of the system with any of the triazenes did not enhance biphenyl 2-hydroxylation. The results indicate that the biphenyl test is not successful with triazene compounds. It is not known whether these carcinogens interfere with the fluorimetric methodology or whether each triazene or its cleavage product and/or metabolite specifically interferes with hydroxylation of the biphenyl substrate. (15 refs)

- 79-1391** Mutagenicity of Metronidazole (Letter to Editor). (Eng) Hartley-Asp, B. (Aktiebolaget Leo Res. Labs., S-251 00 Helsingborg, Sweden). *Lancet* 1(8110): 275; 1979.

Chromosome analysis in 12 patients receiving metronidazole (MN) therapy for vaginal trichomoniasis (200 mg 3x/day for 7 days) revealed no increase in any chromosomal aberration type. However, the range of chromatid aberrations during and after treatment was larger than that before treatment; this was due to a pronounced increase found in two patients, one during and the other after treatment. These studies indicate MN does not have chromosome-breaking activity during the short-term treatment for vaginal trichomoniasis. (8 refs)

- 79-1392** Actions of an Antispermatic, but Non-mutagenic, Indenopyridine Derivative in Mice and *Salmonella typhimurium*. (Eng) Matter, B. E. (Biological and Medical Res. Div., Sandoz Ltd., Basel, Switzerland); Jaeger, I.; Suter, W.; Tsuchimoto, T.; Deyssenroth, H. *Mutat Res* 66(2): 113-127; 1979.

Following single po administration to CD-1 mice, the indenopyridine derivative (4aRS,5SR,9bRS)-2-ethyl-1,3,4,4a,5,9b-hexahydro-7-methyl-1-5-p-tolyl-2H-indeno(1,2-c)pyridine hydrochloride produced long-lasting inhibition of spermatogenesis at dose levels of 10 mg/kg and higher. Testes wts were reduced from days 2 to 217 after treatment, and males showed partial or total sterility at 3-6 wk following treatment, with full recovery at 7-29 wk. The compound showed no indications of dominant lethality or mutagenic potentiality. (14 refs)

- 79-1393** Karyotype and Tumorigenicity of 1-Methylguanine-transformed Chinese Hamster Cells. (Eng) Trewyn, R. W. (Dept. Biochemistry, Univ. Colorado Medical Center, Denver, CO, 80262); Kerr, S. J.; Lehman, J. M. *J Natl Cancer Inst* 62(3): 633-638; 1979.

Chinese hamster embryo cells transformed with the transfer RNA catabolite 1-methylguanine were characterized by Giemsa-banded karyotyping and by their tumorigenic potency in athymic nude mice (10^6 cells sc into each flank). All seven 1-methylguanine-transformed cell lines were hyperdiploid with a modal chromosome number of 23. Three of these lines had an additional marker chromosome derived from the long (q) arm of chromosome 4, and they had alterations of chromosome 5 as well. Two of these three cell lines were tumorigenic. Nonrandom chromosome changes were observed in the other four transformed cell lines, and these changes included the addition of all or a portion of chromosome 6. One of these cell lines was also tumorigenic in nude mice. The three tumorigenic lines gave rise to fibrosarcomas or histiocytomas with local invasion and no evidence of metastasis within 2-6 wk. Specific cytogenetic changes were observed in most of the 1-methylguanine-transformed popu-

lations, in contrast to the karyotypic heterogeneity of a benzo(a)pyrene-transformed cell line. (11 refs)

- 79-1394 Enhancement of Gastric Carcinogenesis in Dogs Given N-Methyl-N'-nitro-N-nitrosoguanidine Following Vagotomy.** (Eng) Fujita, M. (Dept. Oncologic Surgery, Res. Inst. Microbial Diseases, Osaka Univ., Yamada-kami, Suita, Osaka 565, Japan); Takami, M.; Usugane, M.; Nampei, S.; Taguchi, T. *Cancer Res* 39(3): 811-816; 1979.

An attempt was made to improve the induction of gastric cancer in dogs by performing selective vagotomy (Va-x) without the gastric drainage procedure before administration of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG). Twenty dogs were divided into two groups of 10 dogs (5 beagles and 5 mongrels). The control group received MNNG alone. The experimental group was vagotomized 2 mo before administration of MNNG. MNNG soln (50 µg/ml) was administered in the drinking water for 12 mo. In the vagotomized group, gastric adenocarcinomas were induced in all of eight effective dogs, whereas in the control group they were seen in 6/8 dogs. The gastric cancer was multiple in many dogs, but most of the lesions remained in the early stage. The total number of tumors induced in the Va-x and control groups was 42 and 16, respectively. Va-x resulted in the production of more-advanced cancers. One lesion in the control group and four in the Va-x group were advanced cancers invading the serosa. Advanced gastric cancers with metastases to the liver, lymph nodes, and lungs developed exclusively in two vagotomized dogs. Gastric acid secretion of the vagotomized dogs, measured after termination of MNNG was reduced to an av of one-fourth that of the controls. The possible role of Va-x in the enhancement of gastric carcinogenesis in dogs by MNNG is discussed in terms of the inactivation of MNNG in gastric juice and the ulcerogenic action of the carcinogen in the gastric mucosa. - 79-1395 Volatile N-Nitrosamines in the Urine of Normal Donors and of Bladder Cancer Patients.** (Eng) Kakizoe, T. (Urology Div., Natl. Cancer Center Hosp., 5-1-1 Tsukiji, Chuo-ku, Tokyo 104, Japan); Wang, T. T.; Eng, V. W.; Furrer, R.; Dion, P.; Bruce, W. R. *Cancer Res* 39(3): 829-832; 1979.

Urine samples from 27 male donors and 4 bladder cancer patients were analyzed for the presence of volatile N-nitrosamines by gas-liquid and high-pressure liquid chromatography interfaced to a thermal energy analyzer. Of 50 samples from normal men, 10 contained nitrosodimethylamine (0.02-0.10 µg/liter), 6 contained nitrosodiethylamine (0.02-3.10), 9 contained nitrosomorpholine (0.06-0.67), and none contained nitrosodibutylamine. Of four samples from the bladder cancer patients, two contained nitrosodimethylamine (0.32 and 0.70) and nitrosodibutylamine (0.35 and 0.66). Two had no nitrosamines in their urine samples. Cigarette smoking did not appear to be related to the pattern or amount of urinary volatile

N-nitrosamines. The possibility that the N-nitrosamines arise from the diet or from endogenous sources is considered. (19 refs)

- 79-1396 Elevation of Extrahepatic Glutathione S-Transferase and Epoxide Hydratase Activities by 2(3)-tert-Butyl-4-hydroxyanisole (BHA) (Meeting Abstract).** (Eng) Benson, A. M. (Dept. Pharmacology, Johns Hopkins Medical Inst., Baltimore, MD, 21205); Cha, Y. N.; Bueding, E.; Heine, H. S.; Talalay, P. *Fed Proc* 38(3, part 1): 506; 1979. (no refs)

- 79-1397 Photomutagenesis by Chlorinated Phenothiazine Tranquilizers.** (Eng) Jose, J. G. (Sch. Optometry, Univ. California, Berkeley, CA, 94720). *Proc Natl Acad Sci USA* 76(1): 469-472; 1979.

Several chlorinated and nonchlorinated phenothiazines were assayed for mutagenicity in the *Salmonella typhimurium* test system with and without exposure to near-UV irradiation. All of the chlorinated derivatives tested (chlorophenothiazine, chlorpromazine, compazine, and perphenazine) were mutagenic with irradiation, but the nonchlorinated derivatives were not. None of the phenothiazines were mutagenic in the dark. The most reactive phenothiazine was chlorpromazine, which was further analyzed with several different *Salmonella* strains to characterize the nature of the photoinduced mutagenicity. Mutagenicity was observed only in strains that lacked excision repair of DNA (eg, strains TA2637 and TA1537), and it was elevated in strains that contained the plasmid pKM101 (TA2637), which may enhance error-prone repair. Similar strain sensitivity was observed with Compazine. Based on these findings and the relationship between mutagenesis and cancer, it is suggested that the nonchlorinated phenothiazine derivatives be used for medical purposes whenever possible. (29 refs)

- 79-1398 Hematotoxicity of Inhaled Benzene to Sprague-Dawley Rats and AKR Mice at 300 ppm.** (Eng) Snyder, C. A. (A. J. Lanza Labs., New York Univ., Inst. Environmental Medicine, Tuxedo, NY, 10987); Goldstein, B. D.; Sellakumar, A.; Wolman, S. R.; Bromberg, I.; Erlichman, M. N.; Laskin, S. *J Toxicol Environ Health* 4(4): 605-618; 1978.

Sprague-Dawley rats exposed to 300 ppm benzene vapor for 6 hr/day, 5 days/wk, for life exhibited lymphocytopenia, mild anemia, and moderately decreased survival. AKR/J mice exposed to the same regimen showed severe lymphocytopenia and anemia accompanied by granulocytosis and reticulocytosis. Survival and wt gain were also significantly decreased. No indications of a leukemic or preleukemic response were observed in either species. (35 refs)

- 79-1399 Effect of Hexestrol on the Breast of Menopausal Women.** (Ger) Kubista, E. (I. Univer-

sitats-Frauenklinik, Spitalgasse 23, A-1090 Vienna, Austria); Grunberger, W.; Wolf, G. *Wien Med Wochenschr* 129(1): 16-19; 1979.

The effect on the breast of hexestrol substitution therapy (50 mg im for ≥ 12 mo) after ovariectomy and hysterectomy was studied in 167 menopausal women (av age 46.6 yr) over a 2.5-yr period. One hundred and seventy-nine untreated menopausal women (av age 47.9 yr) served as controls. Mammography and thermography revealed no differences between the two groups. Adenomatosis was found in two patients in the control group, but in none of the treated patients. Hexestrol treatment caused no changes in blood clotting compared with controls. The findings indicate that hexestrol is acceptable for substitution therapy in menopause. (16 refs)

- 79-1400 Cytospectrophotometric Investigation of Cytoplasmic RNA in Regenerating and Neoplastic Livers.** (Fre) Moulin-Camus, M. C. (Institut du cancer de Montreal, Centre hospitalier Notre-Dame, Montreal, Quebec, Canada); Daoust, R. *Rev Can Biol* 37(4): 235-255; 1978.

A quantitative cytospectrophotometric investigation was made of cytoplasmic hyperbasophilia in the foci of neoplastic transformation and hepatic tumor cells of male Wistar rats fed a protein-free diet containing 4-dimethylaminoazobenzene (DAB: 0.06% of diet) for 120-150 days, and in the regenerating liver of normal rats subjected to partial hepatectomy. The cells were stained with methylene blue. The two-fold increase in the dye-binding capacity of the cytoplasmic RNA of the tumor cells and neoplastic foci was found to be primarily due to a qualitative alteration resulting in an increased affinity for basic dyes and to an increase in the nuclear-cytoplasmic ratio. This type of hyperbasophilia differed radically from the weak variations in basophilia observed in normal regenerating liver and the hyperplastic liver parenchyma of the DAB-treated rats. In these cases, the changes appeared to be related mainly to de novo RNA synthesis. Biochemical assays of cellular fractions indicated that ribosomes are the organelles responsible for the hyperbasophilic properties of hepatocytes in areas of neoplastic transformation. (51 refs)

- 79-1401 Impairment of Tyrosine Aminotransferase Induction by Hydrocortisone in the Liver of Rats Treated with o-Aminoazotoluene.** (Rus) Kaledin, V. I. (Inst. Cytology and Genetics, Novosibirsk, USSR); Glazko, T. T.; Zakharova, N. P. *Dokl Akad Nauk SSSR* 244(1): 233-237; 1979.

The effect of the carcinogenic dye o-aminoazotoluene (OAT) on hydrocortisone-induced tyrosine aminotransferase (TAT) activity was studied in 2- to 3-mo-old DD and CC57BR mice. DD mice are sensitive to the hepatocarcinogenic effect of OAT and CC57BR mice are resistant. Animals were inoculated ip with OAT and, 20 hr later, with hydrocortisone (2.5 or 12.5 mg/100 g). Hydrocortisone alone increased TAT ac-

tivity: 5 hr after injection with 2.5 mg/100 g, there was a 4.6-fold increase in DD mice and a 3.5-fold increase in CC57BR mice. OAT caused a 1.75-fold decrease of TAT induction in DD mice and a 1.2-fold decrease in CC57BR mice. (15 refs)

- 79-1402 Chromatin-Associated Low Molecular Weight RNA Released into the Liver Cytoplasm in Rats Fed 3'-Methyl-4-dimethylaminoazobenzene (3'-MeDAB) (Meeting Abstract).** (Eng) Patel, N. T. (Univ. Texas Medical Branch, Galveston, TX, 77550); Holoubek, V. *Fed Proc* 38(3, part 1): 499; 1979. (no refs)

- 79-1403 Betel Nuts, Arecaidine, and Oral Cancer (Letter to Editor).** (Eng) Ashby, J. (Central Toxicology Lab., Imperial Chemical Industries, Ltd., Alderley Park, Macclesfield, Cheshire SK10 4TJ, England); Styles, J. A.; Boyland, E. *Lancet* 1(8107): 112; 1979.

The results of an in vitro assay of the carcinogenicity of arecaidine and arecoline, which are present in betel nuts, are reported. Both alkaloids gave an almost identical positive response in a cell-transformation assay, underlining their apparent bioequivalence. (9 refs)

- 79-1404 Metabolism of Drugs and Carcinogens in Man: Antipyrine Elimination as an Indicator.** (Eng) Kalamegham, R. (Natl. Inst. Nutrition, Indian Council Medical Res., Jamai Osmania P.O., Hyderabad 500 007, A. P., India); Krishnaswamy, K.; Krishnamurthy, S.; Bhargava, R. N. *Clin Pharmacol Ther* 25(1): 67-73; 1979.

The suitability of antipyrine (AP) in predicting drug and carcinogen metabolism was investigated by studying the in vivo AP elimination rate (K_e) and the in vitro metabolism of drugs and carcinogens in liver preparations in the same individual. The test subjects were 20 men with chronic duodenal ulcer that were scheduled for gastrojejunostomy. Most of the men smoked cigarettes or beedies (tobacco rolled in dry leaves); none took any alcohol during the previous year. The half-life and K_e of AP were determined by linear regression analysis in all subjects prior to surgery. AP (18 mg/kg) was administered under fasting conditions, and plasma levels 4, 6, 9, and 12 hr later were determined spectrophotometrically. Both the in vitro enzyme activities and the K_e showed wide variations. Significant correlations were observed only between aryl hydrocarbon hydroxylase (AHH) activity and AP K_e ($p < 0.05$), aniline hydroxylase activity ($p < 0.001$), and γ -glutamyl transferase activity ($p < 0.01$). Aminopyrine N-demethylase did not correlate with any of the parameters studied. Although the degree of correlation between AP K_e and AHH was statistically significant, it was not satisfactory for predictive purposes. This study points out some of the problems and limitations of in vivo-in vitro comparisons and it confirms earlier doubts on the usefulness of AP as a proto-

type drug for predicting drug and carcinogen metabolism in humans. (30 refs)

79-1407 Mutagenicity of 19 Major Graphic Arts and Printing Dyes. (Eng)

Milvy, P. (Environmental Sciences Lab., Mount Sinai Sch. Medicine, City Univ. New York, New York, NY, 10029); Kay, K. *J Toxicol Environ Health* 4(1): 31-36; 1978.

The mutagenicity of 19 dyes, representative of those used most extensively in the graphic arts and printing industry and for which no carcinogenic data exist, was tested in *Salmonella typhimurium* strains TA98, TA1538, and TA1535, with and without microsomal activation. The microsomes were prepared from Aroclor 1254-induced male Swiss Webster mice. Two of the 19 dyes were weakly mutagenic. Para Red, a derivative of 1-phenylazonaphthalene, was mutagenic with microsomal activation and Dinitroaniline Orange, a derivative of azobenzene, was directly mutagenic. Both dyes were frameshift mutagens; their planar aromatic structure probably permits them to complex with the DNA double helix. It is suggested that the carcinogenic potential of these two dyes be evaluated in animal studies. (5 refs)

79-1408 Evidence for the Absence of a Mutagenic Effect of Methadone in Germ Cells of *Drosophila melanogaster*. (Eng)

Zimmering, S. (Div. Biology and Medicine, Brown Univ., Providence, RI, 02912). *Mutat Res* 66(2): 133-134; 1979.

Mutagenicity studies revealed that methadone (0.1 or 1.0 mg/ml) produced no sex-linked recessive lethals when either fed to or injected in adult male *Drosophila melanogaster*. Similarly, the results of tests for chromosome breakage and nondisjunction gave no evidence of a mutagenic effect. (no refs)

79-1409 Transfer of Polychlorinated Biphenyls from Mothers to Foetuses and Infants. (Eng)

Masuda, Y. (Daiichi Coll. Pharmaceutical Sciences, Minami-Ku, Fukuoka 815, Japan); Kagawa, R.; Kuroki, H.; Kuratsune, M.; Yoshimura, T.; Taki, I.; Kusuda, M.; Yamashita, F.; Hayashi, M. *Food Cosmet Toxicol* 16(6): 543-546; 1978.

The transfer of polychlorinated biphenyls (PCB's) through the placenta and maternal milk was studied by analyzing blood, milk, adipose tissue, and other tissues from mothers, fetuses, and infants for PCB's. PCB levels in maternal blood were approx four-fold higher than those in cord blood. PCB levels in the maternal blood were weakly correlated with those in cord blood and strongly correlated with those in maternal adipose tissue. However, the correlation coefficient between maternal adipose tissue and cord blood samples was not significant. PCB levels in blood samples from infants were significantly higher than those in the maternal blood, the maternal blood levels being significantly correlated with those in the fat in the maternal milk. PCB levels in infant blood were not significantly correlated with those in the maternal blood or milk. PCB concentrations in the adipose tissue, liver, and adrenals from stillborn infants were less than one-tenth of the corresponding values for adults. The data suggest that transfer of PCB's via the milk is much more significant than placental transfer. There appears to be a placental barrier against PCB's. (16 refs)

79-1410 Influence of Genetic Population Structure on the Results of Chronic Toxicity Studies. (Eng)

Littlefield, N. A. (Natl. Center Toxicological Res., Jefferson, AR, 72079); Kodell, R. L. *J Toxicol Environ Health* 5(1): 121-129; 1979.

Offspring from a BALB/cStCrIFC3Hf/Nctr male and C567BL/6JfC3Hf/Nctr female cross were used to produce a homogeneous (F₁) strain, and brother-sister mating of the F₁ population was used to produce a heterogeneous (F₂) strain of mice, both having essentially the same gene pool but with different distributions. These mice were exposed over their life-span to benzidine dihydrochloride (0-160 ppm in the drinking water) in an experiment to provide data demonstrating the relative variability about the mean of response to a carcinogen in genetically homogeneous and heterogeneous groups of mice. There were four groups of mice divided by sex and by F₁ and F₂ population, and each group totaled 648 mice; 72 mice were used for each dose level within each group. All dose levels were toxic, as indicated by body wt loss. F₁ mice were significantly heavier and had a lower mortality rate than the F₂ animals. There were 82 animals left after termination of the study at 33 mo, 66 controls and 16 treated mice; 59 were F₁ and 23 were F₂. These ratios are consistent with the data showing that F₂ mice are more sensitive and have shorter life-spans than F₁ mice. Thus, the genetic constitution of research animals should be an important consideration in toxicological investigations. Although the same alleles existed in these two populations, their distribution, identical in F₁ and randomly distributed in F₂, resulted in significant differences between the two populations in body wt and mortality. (9 refs)

79-1411 Characterization of Chronic N,N'-F1-Diacetylbenzidine-induced Nephropathy. (Eng)

Zimmerman, S. W. (Dept. Medicine, Univ. Wisconsin Center

Health Sciences, Madison, WI, 53706). *Am J Pathol* 94(2): 285-300; 1979.

Glomerular (GM) lesions induced in female Sprague-Dawley rats by chronic N,N'-diacetylbenzidine (DAB) administration were characterized with regard to amount of proliferation and "crescent" formation and their relationship to urinary protein excretion. The rats received weekly ip injections of 0.1-0.25 ml of a suspension of 1 g DAB in 10 ml ethanol for up to 20 wk. Some of the rats underwent left nephrectomy (Nx) prior to treatment. Animals were killed 1.5-35 wk after receiving 45-230 mg DAB. Those with the most significant GM lesions had significant proteinuria (PU). DAB dose did not appear to relate to histologic alterations--several rats received 75-180 mg DAB but failed to demonstrate dramatic histologic alterations or significant PU. Significant PU occurred at ± 10 wk, and it was enhanced by prior unilateral Nx. GM epithelial cell vacuolization and cyst formation were marked in proteinuric rats. Focal GM sclerosis and synechia were present, but proliferative crescent formation was not. GM fibrinogen was noted, but no immunoglobulins or complement was detected by immunofluorescence microscopy. GM epithelial cell cysts and disruption were seen ultrastructurally, but there were no electron-dense deposits. Tubular basement membranes were focally thickened and wrinkled, and max urine osmolality was decreased. None of the animals developed renal insufficiency. Parenteral DAB-induced renal disease is different from the crescentic glomerulonephritis noted in rats fed DAB, and it has similarities to an experimental model of aminonucleoside-induced focal sclerosis, supporting the theory of primary GM epithelial cell injury mediating PU and focal sclerosis. (20 refs)

79-1412 Azathioprine-induced Lymphocytic Neoplasms of NZB Mice Lack Ecotropic Murine Leukemia Virus. (Eng) Harvey, J. J. (MRC Clinical Res. Centre, Harrow, Middlesex, England); East, J.; Katz, F. E. *Int J Cancer* 23(2): 217-223; 1979.

The concept that the presence of an ecotropic viral genome is an essential cocarcinogenic factor for the induction of lymphocytic (LC) malignancy was investigated in New Zealand Black (NZB) mice, in which LC neoplasms were induced by long-term treatment with the immunosuppressant azathioprine (ATP: Imuran). Im injection of 2.5 mg/25 g ATP 3x/wk for 4 wk, 2x/wk during wk 5, and 1x/wk for up to 6 mo resulted in LC lymphomas 6-7 mo after the start of treatment. These malignancies were distinct from the reticulum cell tumors that occur spontaneously in this strain, and they were readily transplantable to NZB or histocompatible BALB/c recipients. In addition, leukemic cells stored in liquid nitrogen for 6 yr proliferated rapidly when injected into newborn syngeneic mice. Virus filtrates prepared from donor leukemic tissues were nonpathogenic when injected into newborn C3H mice. Xenotropic, but not ecotropic, murine leukemia virus was detected in leukemic tissues of some donor and recipient NZB mice when tested in vitro by cocultivation with permissive cell lines, genome rescue, and by XC and

viral polymerase assays. These findings indicate a need to reassess the concept that LC malignancies and, perhaps, other types of malignancies induced by methods other than deliberate virus infection are necessarily due to activation of an ecotropic viral genome. (48 refs)

79-1413 Effect of Mutagens, Chemotherapeutic Agents and Defects in DNA Repair Genes on Recombination in F' Partial Diploid *Escherichia coli*. (Eng) Norin, A. J. (Montefiore Hosp. and Medical Center, Albert Einstein Coll. Medicine, C-416, 111 E. 210th St., Bronx, NY, 10467); Goldschmidt, E. P. *Mutat Res* 59(1): 15-26; 1979.

The effects of mutagens, chemotherapeutic agents that inhibit DNA synthesis, a DNA polymerase I mutation, and a UV excision-repair mutation on recombination in F' partial diploid (F30) *Escherichia coli* were compared. The assay involved determining the proportion of His⁺ homogenote recombinants that arose from a His⁺ heterogenote. The mutagens increased the percentage of haploid and auxotrophic colonies, but Hfr recombinants were not observed. At least 75% of the recombinants were homozygous for histidine alleles that were present on the F' plasmid (exogenote) of the parental heterogenote rather than for histidine alleles on the chromosome. Mutagens, agents that inhibit DNA synthesis (2-aminopurine and methotrexate), and a defective DNA polymerase I gene (*polA1*) increased the frequency of non-reciprocal recombination. A defect in the ability to excise thymine dimers, *uvrC34*, did not increase spontaneous non-reciprocal recombination. However, UV irradiation but not methyl methanesulfonate (MMS) induced greater recombination in this excision-repair-defective mutant than in DNA-repair-proficient strains. Mutagenic agents, with the exception of ethyl methanesulfonate (EMS), induced greater increases in recombination than the DNA synthesis inhibitors or the *polA1* mutation. EMS was more mutagenic but less recombinogenic than MMS. One explanation for these results is that DNA synthesis inhibition increases recombination by prolonging the lifetime of naturally occurring single-stranded regions in replicative intermediates of the DNA. Mutagens that cause the rapid breakdown of DNA may, in addition, introduce lesions into the genome that increase the number of single-stranded regions, thus inducing even higher frequencies of recombination. (37 refs)

79-1414 Transport and Metabolism of Methotrexate in Normal and Resistant Cultured Rat Hepatoma Cells. (Eng) Galivan, J. (Div. Labs. and Res., New York State Dept. Health, Albany, NY, 12201). *Cancer Res* 39(3): 735-743; 1979.

The transport and metabolism of the antifolate drug methotrexate (MTX) were examined in monolayer cultures of a continuous cell line derived from the Reuber H35 hepatoma. The H35 cells had a doubling time of approx 19 hr and could not grow in the presence of 3×10^{-6} M MTX. The cells exhibited a linear uptake of MTX that lasted for 4-6 hr and reached

a steady state after approx 16 hr. The uptake was saturable, with a max rate of 1.1 nanomoles/min/g cell protein at $\geq 18 \mu\text{M}$ MTX. 5-Methyltetrahydrofolate markedly inhibited uptake at an equimolar concentration, but folic acid exerted no effect at a five-fold excess. Once inside the cell, MTX was rapidly converted to its polyglutamate derivatives with a conversion $> 90\%$ when the intracellular concentration was $> 2 \mu\text{M}$. Resistant sublines were developed by culturing H35 cells in increasing concentrations of MTX. These cells were similar to the parent cells in levels of dihydrofolate reductase, thymidylate synthetase, and the extent that MTX could be converted to its polyglutamate derivatives. They appeared to differ from normal cells in not having the capacity for the extended linear uptake that is observed with normal cells. As a result, there was a greatly reduced concentration of MTX and its polyglutamates at steady state. These results suggest that the cells become resistant as a result of a stable change in the transport system for MTX, but the mechanism of this process is not yet understood. (61 refs)

- 79-1415 Transplacental Effects of Chemical Mutagens Detected by the Micronucleus Test.** (Eng) Cole, R. J. (Developmental Genetics Group, Sch. Biological Sciences, Univ. Sussex, Falmer, Brighton, England); Taylor, N. A.; Cole, J.; Arlett, C. F. *Nature* 277(5694): 317-318; 1979.

Chromosome damage in fetal mouse tissue following transplacental exposure to chemicals that require metabolic activation was studied. A kinetic model was constructed that predicted that the transplacental and maternal effects of chromosome-damaging agents could be compared by measuring the incidence of polychromatic RBC containing micronuclei 12-30 hr after exposure. If each of the target cells received damage leading to formation of a single micronucleus, the max incidence of polychromatic RBC containing micronuclei in fetal liver and bone marrow would be about 25%. The frequency of polychromatic RBC in the blood was predicted to be about 60% of the peak in the fetal liver. Pregnant Swiss albino mice were inoculated ip with mitomycin C (2 mg/kg) or procarbazine hydrochloride (10-100 mg/kg). With both agents, damage to the fetal liver was greater than that to the adult bone marrow. After mitomycin C, the spontaneous incidence of micronucleated RBC was 0.16% in the adult bone marrow, 0.4% in the fetal liver, and 0.24% in the fetal blood. These results establish the usefulness of the RBC micronucleus test applied to prenatal mice. (12 refs)

- 79-1416 Isolation of Polyaromatic Hydrocarbons from Whole Smoke Condensate: A Simple Two-Step Procedure.** (Eng) Levins, R. J. (Res. Center, P.O. Box 26583, Richmond, VA, 23261); *Chromatographia* 11(12): 736-741; 1978.

A rapid, simple, two-step procedure for the isolation of polyaromatic hydrocarbons (PAHs) from whole smoke con-

densate (WSC) is described. A crude PAH fraction is isolated by preparative thin-layer chromatography, and is then further enriched by gel permeation chromatography on Sephadex LH-20. A complete analysis, including a gas chromatographic temperature-programmed profile of the PAH fraction, can be performed in less than 8 hr, permitting the comparison of the gas chromatographic scans of the PAH fractions from a number of WSCs in a relatively short time. (13 refs)

- 79-1417 Level of Pesticide Residues in Beer.** (Fre) Gouraud, J. (Ecole nationale superieure des industries agricoles, 59509 Douai, France); Scriban, R. *Ann Nutr Aliment* 32(5): 975-979; 1978.

A method is presented for the extraction, purification, and gas chromatographic analysis of several pesticides, including dieldrin and 1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane (DDT), in beer. (2 refs)

- 79-1418 Metabolism of 7,12-Dimethylbenz[a]anthracene and Its Methylhydroxylated Derivatives: Formation of Phenolic Metabolites at the 2-Positions (Meeting Abstract).** (Eng) Yang, S. K. - 79-1420 A Quantitative Determination of the Covalent Binding of a Series of Polycyclic Hydrocarbons to DNA in Mouse Skin.** (Eng) Phillips, D. H. (McArdle Lab. Cancer Res., Univ. Wisconsin Medical Center, Madison, WI, 53706); Grover, P. L.; Sims, P. *Int J Cancer* 23(2): 201-208; 1979.

The binding of seven ^3H -labeled polycyclic hydrocarbons to DNA in C57BL mouse skin following topical application was studied. DNA isolated from the treated areas was hydrolyzed enzymically to deoxyribonucleosides, and the products were chromatographed on Sephadex LH20 columns. The levels of binding of hydrocarbon to DNA were determined from the amounts of radioactivity eluted from Sephadex LH20 columns in those fractions containing hydrocarbon-DNA adducts. Tritium incorporation into normal deoxyribonucleosides was examined by rechromatography of material on AG50W-X4 columns and in some instances it was found to account for a substantial proportion of the total radioactivity associated with DNA samples. Following treatment of mice with 1 micromole of hydrocarbon/mouse, 7,12-dimethylbenz(a)anthracene, the most potent carcinogen studied, became bound to DNA to the greatest extent [43 picomoles

(pmol)/mg DNA] Benzo(a)pyrene and 3-methylcholanthrene, the next most active compounds, became bound to DNA to similar extents (27 and 25 pmol/mg DNA), as did 7-methylbenz(a)anthracene (25 pmol/mg DNA), although it is a less active compound. Dibenz(a,h)anthracene, another moderately active hydrocarbon, became bound to DNA to the extent of 15 pmol/mg DNA, and the very weakly active compounds benz(a)anthracene (2 pmol/mg DNA) and dibenz(a,c)anthracene (10 pmol/mg DNA) became bound to DNA to the lowest extents. Dibenz(a,h)anthracene differed from the other hydrocarbons in showing a max level of binding 72 hr after treatment, compared with 19-24 hr for the other compounds. (33 refs)

- 79-1421 Role of Acid-Base Balance in Tumor Manifestation: An Experimental Study in Two-Stage Skin Carcinogenesis.** (Eng) Stenback, F. (Dept. Pathology, Univ. Oulu, Oulu, Finland); Ryan, W.; Curtis, G. *IRCS Med Sci (Cancer)* 7(1): 45; 1979.

A study of the effect of prolonged metabolic alkalosis or acidosis on the induction of skin tumors in female Swiss mice by 7,12-dimethylbenz(a)anthracene + phorbolmyristate acetate demonstrated a significant increase in the number of tumors and tumor-bearing animals associated with alterations in the acid-base balance. Although both bicarbonate-induced alkalosis and ammonium chloride-induced acidosis increased tumorigenesis, the effect was more pronounced with the former. (2 refs)

- 79-1422 Influence of Dietary Fat on Microsomal Monooxygenases: Possible Relationship to 7,12-Dimethylbenzanthracene (DMBA)-induced Mammary Cancer (Meeting Abstract).** (Eng) Rikans, L. E. (Dept. Pharmacology, Univ. Oklahoma Health Science Center, Oklahoma City, OK, 73104); Gibson, D. D.; McCay, P. B. *Fed Proc* 38(3, Part 1): 365; 1979. (1 ref)

- 79-1423 Effect of Reserpine on the Incidence of 9,10-Dimethyl-1,2-benzanthracene-induced Tumors in Pinealectomized and Thymectomized Rats.** (Ger) Lapin, V. (Institut für Krebsforschung, Universität Wien, Borschkegasse 8a, A-1090 Vienna IX, Austria). *Onkologie* 1(1): 2-5; 1978.

The effects of neonatal pinealectomy (Pi-x) and/or thymectomy (Th-x) and reserpine (RP) treatment on tumor induction by 9,10-dimethyl-1,2-benzanthracene (DMBA) were studied in male and female Wistar rats. Group 1 received DMBA (3 doses of 50 mg/kg via gastric intubation at 10-day intervals) and then RP (100 µg/kg/day sc for 40 days) starting 1 mo after the first DMBA dose. Group 2 received DMBA and then physiological saline soln instead of RP. Group 3 received RP only. In Group 1, tumor incidence was 12/19 in nonoperated rats, 15/15 in Pi-x rats, 10/15 in Th-x rats, and 6/6 in Pi-x + Thy-x rats. In Group 2, tumor incidence was

5/12 in nonoperated animals, 5/12 in Pi-x rats, 7/16 in Th-x rats, and 4/6 in Pi-x + Th-x rats. In Group 3, no tumors were found in the four subgroups. Among the DMBA-treated animals, survival was shortest in the Pi-x group (239 days vs 310-319 days in Th-x and intact animals). Hormone-dependent tumors of the breast and auditory meatus were most frequent. Nephroblastoma was found in two Th-x rats. Leukemia was seen sporadically in the DMBA-treated animals (incidence, 6.74%); however, leukemia does not occur spontaneously in these rats. Leukemia incidence was highest in the Pi-x rats in Group 1. The findings indicate that the carcinogenic effect of DMBA is not enhanced substantially by neonatal Pi-x and that neonatal Th-x does not increase the susceptibility of rats to the carcinogenic effect of DMBA. Although RP alone had no harmful or carcinogenic effect, it increased the incidence of DMBA-induced tumors in Pi-x rats. (14 refs)

- 79-1424 In Vivo and In Vitro Studies of Experimental Ovarian Adenocarcinoma in Rats.** (Eng) Sekiya, S. (Dept. Obstetrics and Gynecology, Chiba Univ. Sch. Medicine, Inohana 1-8-1, Chiba 280, Japan); Endoh, N.; Kikuchi, Y.; Katoh, T.; Matsuura, A.; Iwasawa, H.; Takeda, B.; Takamizawa, H. *Cancer Res* 39(3): 1108-1112; 1979.

The induction of adenocarcinoma-type ovarian tumors in female Sprague-Dawley rats by the "clipping" method using the carcinogens 7,12-dimethylbenz(a)anthracene (DMBA) and 20-methylcholanthrene (20-MC) is described, along with the establishment of two cloned cell lines from these tumors in vitro. Silk sutures were soaked in a melted mixture of carcinogen:beeswax (1:3) and allowed to dry, and they were then inserted into the right side of the ovarian parenchyma by a surgical needle through a single middorsal incision and knotted. The av amount of carcinogen per suture was 1.92 mg. Tumor development was checked by weekly palpation over a 50-wk period. Tumors occurred in 36/75 DMBA-treated rats, and 29/36 tumors were adenocarcinomas. Tumors occurred in 6/31 20-MC-treated rats, but only 1/6 tumors was an adenocarcinoma. In attempts to culture adenocarcinoma tissue specimens, initial growth was found to be strongly influenced by the specific lactate dehydrogenase activity of the tumor tissues. The mean specific activity of the successful cases was 1,020 units/g protein, vs 365 units for the failures. Two cloned cell lines were isolated, both of which were epithelioid. When approx 1.5×10^6 cells of these lines were injected sc into isologous newborn rats, tumors developed after 6 wk in 5/6 and 3/7 rats, respectively. The tumors were undifferentiated adenocarcinomas. (13 refs)

- 79-1425 Compartment Model of Carcinogenic Promoter Activity.** (Eng) Lipetz, P. D. (Ohio State Univ., Columbus, Ohio, 43210). *Diss Abstr Int B* 39(8): 3661; 1979. (no refs)

- 79-1426 Quantitative Correlation between In Vitro and In Vivo Activities of Phorbol Esters.** (Eng)

Driedger, P. E. (Dept. Pharmacology, Harvard Medical Sch., Boston, MA, 02115); Blumberg, P. M. *Cancer Res* 39(3): 714-719; 1979.

The effects of various phorbol derivatives on surface large external transformation-sensitive glycoprotein (LETSP) levels and on deoxyglucose (DG) transport in normal chicken embryo fibroblasts were determined. Dose-response data indicated that with one exception [phorbol 12,13-dibenzoate (PDB)], these derivatives all caused a comparable max decrease in LETSP, whereas their half-maximally effective doses (ED_{50} 's) varied over a range of four orders of magnitude. Good quantitative correlation was obtained between these ED_{50} 's and the inflammatory potencies (quantity causing ear inflammation in 50% of a group of treated mice, ID_{50} 's) of these derivatives in the mouse ear assay. With respect to stimulation of DG transport, the phorbol esters fell into two categories. Phorbol 12-myristate-13-acetate (PMA), phorbol 12,13-diacetate, and phorbol 12,13,20-triacetate showed ED_{50} 's for stimulating DG transport that closely matched their ED_{50} 's for causing loss of LETSP (and thus their ID_{50} 's in the mouse ear assay). Phorbol 12,13-didecanoate, PDB, and 4-O-methylphorbol 12-myristate-13-acetate were four- to ninefold more potent in stimulating DG transport than in causing LETSP loss. Unlike the phorbol esters, the parent diterpene phorbol and free myristic acid had little effect on DG transport or LETSP levels at concentrations up to 3 and 0.2 millimolar, respectively, above which toxicity was observed. For PMA, the relation between stimulation of DG transport and toxicity was examined. In contrast to a 3.7 nanomolar ED_{50} for stimulation by PMA, inhibition of this stimulation occurred only with an ED_{50} of 3.3 μ M and cell lysis occurred with an ED_{50} of 11 μ M. (51 refs)

79-1428 Plasma Membrane Alterations in Phorbol Myristate Acetate (PMA)-Treated Myogenic Cells (Meeting Abstract). (Eng) Schimmel, S. D. (Dept. Biochemistry, Coll. Medicine, Univ. South Florida, Tampa, FL, 33612); Hallam, T.; Grotendorst, G.; Breiner, J.; Grove, R. I. *Fed Proc* 38(3, Part 1): 665; 1979. (1 ref)

79-1429 Tumor Promoter 12-O-Tetradecanoylphorbol-13-acetate Is Not a Prostaglandin E-Type Agonist. (Eng) Furstenberger, G. (Inst. Biochemistry, German Cancer Res. Center, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Marks, F. *Cancer Lett* 6(2): 73-77; 1979.

The ability of the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) to compete with E-type prostaglandins (PGE) for an established PGE receptor was tested in a com-

petition binding assay using lipocytes prepared from male Wistar rats. In doses up to a 400-molar excess (1,230 nanograms 2×10^{-4} M), TPA could not significantly displace PGE_1 from its receptor in the fat cell membrane. Similar observations were made using receptor preparations from adipose tissue instead of intact fat cells. Under the conditions used, TPA was not chemically altered. These results provide evidence that TPA is not a PGE agonist, at least as far as the PGE_1 receptor of fat cells is concerned. (10 refs)

79-1430 Tumor Development in Organ Transplants Obtained from Carcinogen-exposed Rats. (Eng)

Yarita, T. (Dept. Surgery, Inst. Pulmonary Cancer Res., Sch. Medicine, Chiba Univ., Chiba 280, Japan); Nettesheim, P. *J Natl Cancer Inst* 62(2): 417-424; 1979.

To determine whether carcinogenesis initiated by N-nitrosoheptamethyleneimine (NHMI) in prospective tissue donors is affected by transplantation of target organs by grafting onto isogenic recipients, tumor development in situ and in transplanted tracheas and esophagi was followed 70-80 wk in male F344 rats. Rats were given 15 mg NHMI/kg by intragastric intubation 3x/wk for 5 wk (for a total of 225 mg/kg) or 10 wk (for a total of 450 mg/kg). Carcinogenesis was not disrupted by the transplantation procedure. A dose-response relationship was seen in both systems, and the histopathologic changes developing as a function of time appeared to be similar in transplanted and in situ tracheas and esophagi. The proportion of carcinomas to papillomas in transplanted esophagi was markedly higher however, and the tracheal tumor response gave indications of the same trend. At high carcinogen dose, tumor incidence was 100% in transplanted esophagi and 90% in situ, while tracheal incidence was 20% and 25% in situ and in transplants, respectively. At low dose, only one tracheal tumor developed (in a transplanted organ), and the esophagus tumor incidence was 36% in situ and 100% in transplants. These results indicate that tumor response in heterotropic transplants is enhanced as compared with in situ tumor development. (19 refs)

79-1431 Effect of Alkane Tumor-promoting Agents on Chemically Induced Mutagenesis in Cultured V79 Chinese Hamster Cells. (Eng) Lankas, G. R. (Dept. Environmental Health, Univ. Cincinnati Medical Sch., Cincinnati, OH, 45267); Baxter, C. S.; Christian, R. T. *J Toxicol Environ Health* 4(1): 37-41; 1978.

Linear alkanes with even chain lengths of 6-14 carbon atoms, 1-phenyldodecane (PDD), and 12-O-tetradecanoylphorbol-13-acetate (TPA) were tested in ouabain-resistant mutant V79 Chinese hamster cells for their ability to enhance mutagenesis induced by methylazoxymethanol acetate (MAM). The cells were incubated with MAM (24 μ g/ml) for 24 hr, after which the medium was replaced by fresh medium containing the chemical being tested for promoting activity. n-Hexane, n-decane, n-dodecane, n-tetradecane, and n-hexadecane were tested at 0.12 mM, PDD at 0.7 mM, and TPA

at 1.6 μ M. At these concentrations, none of the alkanes was toxic and MAM-induced toxicity was not affected. No alkane was mutagenic by itself. Enhancement of MAM-induced mutation frequency was observed with n-decane, n-dodecane, and n-tetradecane, but not with n-hexane or n-hexadecane. These results are in good agreement with the relative promoting activities of these agents in mouse skin. TPA and PDD enhanced MAM-induced mutagenesis to a similar degree, indicating that on a molecular basis TPA is approx 400 times more potent than PDD in this system. These results suggest a critical role for mutagenesis in the initiation of carcinogenesis and support the theory that promoters act by inducing changes at the level of the genome, causing expression of latent damage associated with carcinogen-induced mutations. (9 refs)

- 79-1432 5,6-Epoxyretinoic Acid Opposes the Effects of 12-O-Tetradecanoylphorbol-13-acetate in Bovine Lymphocytes.** (Eng) Wertz, P. W. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Kensler, T. W.; Mueller, G. C.; Verma, A. K.; Boutwell, R. K. *Nature* 277(5693): 227-229; 1979.

The synthesis and testing of 5,6-epoxyretinoic acid as an antagonist of the effects of the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) in bovine lymphocytes are reported. For comparison, tests were also conducted with retinoic acid. 5,6-Epoxyretinoic acid inhibited the TPA-accelerated incorporation of choline into the phospholipids of bovine lymphocytes more effectively than did retinoic acid. It was also a more effective inhibitor of ornithine decarboxylase induction by TPA in bovine lymphocytes. Thus, introduction of an epoxide group at the 5,6-position of retinoic acid results in an enhanced ability to oppose certain effects of TPA in bovine lymphocytes. These results do not prove the concept of metabolic activation of retinoic acid, but they are consistent with the suggestion that an activation process may involve epoxidation at the 5,6-position. These results also demonstrate that bovine lymphocytes are a good indicator system for studying the modulation of metabolic processes by phorbol esters and retinoids. (16 refs)

- 79-1433 The Effects of Fatty Acids and Antioxidants in the Culture Medium on Membrane Composition and Properties of the Microsomal Enzymes Aryl Hydrocarbon Hydroxylase and Cytochrome c Reductase of Cultured Liver Cells.** (Eng) Chenery, R. J. (Lab. Toxicology and Pharmacokinetics, Dept. Clinical Pharmacology, Univ. Coll. Hosp. Medical Sch., University St., London WC1E 6JJ, England); McLean, A. E. *Biochim Biophys Acta* 572(1): 9-18; 1979.

The possibility of a role for fatty acids in the control of aryl hydrocarbon hydroxylase (AHH) activity in cell culture was examined using rat liver epithelial cells. Cells grown in medium without serum showed characteristic changes in fatty acid composition and decreased levels of AHH activity. Cell fatty

acid composition was manipulated using albumin-fatty acid complexes. Both gas-liquid chromatographic analysis of fatty acid methyl esters and Arrhenius plots of enzyme activity indicated changes in membrane lipid composition without major changes in AHH activity or inducibility by 1,2-benzanthracene in the presence of the antioxidant butylated hydroxytoluene. The effects of adding palmitate, oleate, linoleate, and arachidonate to the culture medium were also investigated. The saturated and monounsaturated fatty acids were ineffective at altering either basal or induced levels of AHH. In the absence of the antioxidant, both linoleic acid and arachidonic acid caused significant enhancement of AHH activity. Substantial cytotoxic effects were also observed under these conditions. The changes in microsomal AHH activity were independent of changes in cytochrome c reductase. It is concluded that AHH activity in cell culture is not directly related to cell fatty acid composition, but induction by 1,2-benzanthracene can occur with only minute concentrations of essential fatty acids present in the cellular lipids. (34 refs)

- 79-1434 An Appraisal of Relative Airborne Sub-Urban Concentrations of Polycyclic Aromatic Hydrocarbons Monitored Indoors and Outdoors.** (Eng) Butler, J. D. (Dept. Chemistry, Univ. Aston, Birmingham, B4 7ET, England); Crossley, P. *Sci Total Environ* 11(1): 53-58; 1979.

Particle-size distribution and concentration studies of airborne polycyclic aromatic hydrocarbons were conducted at three indoor and three outdoor sites in and around the city of Birmingham, England. The mass median equivalent diameter of total particulate matter was approx 1 μ M at all outdoor sites. At all sites, chrysene concentrations were the highest at 4-7 nanograms (ng)/m³, followed by benzo(a)pyrene and benzo(e)pyrene at 2-4 ng/m³, with coronene less than 1 ng/m³. (9 refs)

Persons with high inducibility of aryl hydrocarbon hydroxylases (AHH) by certain carcinogens, such as benzantracene, methylcholanthrene, and hexobarbital, are considered to be especially likely to develop lung cancer. A comparative study of 50 lung carcinoma patients and 85 tumor-free controls revealed that the incidence of high AHH inducibility was 30% in the cancer patients vs 9.4% in the controls. The incidence of medium inducibility was 66% in the patients and

45.9% in the controls, whereas that of low inducibility was 4% in the patients and 44.7% in the controls. (8 refs)

- 79-1437** Effects of Subcutaneous Administration of 3-Methylcholanthrene and 7,12-Dimethylbenz(a)anthracene on Spontaneous Reticulum Cell Neoplasms in SJL/J Mice. (Eng) Whitmire, C. E. (Toxicology Branch, Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD, 20014). *J Natl Cancer Inst* 62(3): 561-564; 1979.

The interaction of the spontaneous reticulum cell neoplasms (RCN's) associated with SJL/J inbred mice and sc carcinogenesis induced by 3-methylcholanthrene (3-MC) and 7,12-dimethylbenz(a)anthracene (DMBA) was determined. Inbred 4- and 16-wk-old SJL/J mice were treated sc with either 150 or 450 µg 3-MC. No difference was noted in their sc tumor response related to age. Although the incidences of RCN's were the same in the controls for the two age groups, more 16-wk-old animals developed RCN's after carcinogen treatment than did 4-wk-old SJL/J mice. More 16-wk-old mice developed both sc tumors at the site of 3-MC injection and systemic RCN's than did mice treated at 4 wk of age. This incidence was related to the coincidence of the chronological age of the mice for RCN development with the latency for chemical carcinogen-induced sc tumor development. Mice treated with DMBA at 16 wk of age responded in the same way as did those treated with 3-MC. (7 refs)

- 79-1438** Simultaneous Determination of Cellular Mutagenesis and Transformation by Chemical Carcinogens in Fischer Rat Embryo Cells. (Eng) Mishra, N. K. (Microbiological Associates, 5221 River Road, Bethesda, MD, 20016); Wilson, C. M.; Pant, K. J.; Thomas, F. O. *J Toxicol Environ Health* 4(1): 79-91; 1978.

An assay was developed for simultaneous measurement of transformation and induced mutation (ouabain resistance) in Fischer rat embryo (FRE) cells infected with Rauscher leukemia virus (RLV). Virus-positive cells were subcultured 7 days after infection and fed 48 hr later with medium containing the test chemical (day 0). The cells were refed with chemical-containing medium on day 5; the chemical was removed on day 7, and the cultures were passaged serially for 10-12 subcultures. Cells at the third subculture were tested for ouabain resistance. For the transformation assay, the cells were monitored at each subculture for morphological alteration and growth in soft agar. The assay was validated in tests using eight carcinogens [3-methylcholanthrene, dimethylbenz(a)anthracene, benzo(a)pyrene, N-methyl-N'-nitro-N-nitrosoguanidine, 4-nitroquinoline-N-oxide, methylazoxymethanol acetate, N-2-fluorenylacetylacetamide (AAF), and dimethylnitrosamine (DMN)] and five noncarcinogens. All chemicals known to be carcinogenic in rodent bioassays except DMN and AAF induced transformation or mutation. DMN but not AAF could be activated by the addition of rat liver homogenates. All chemicals that produced transforma-

tion also induced a significant increase in ouabain resistance. It is concluded that the simultaneous measurement of drug resistance and transformation is effective for routine screening. (21 refs)

- 79-1439** Growth Retardation in Post-Partum Pups due to Dimethylbenzanthracene (DMBA) Administration in Pregnant Rats. (Eng) Pitkow, H. S. (Dept. Physiological Sciences, Pennsylvania Coll. Podiatric Medicine, Philadelphia, PA, 19107); Citron, A.; Rizen, H.; Davis, R. H. *Pro Pennsylvania Acad Sci* 52(1): 34-36; 1978.

The effect of the carcinogen 7,12-dimethylbenzanthracene (DMBA: 1 mg/day ip during days 8 through 12 of pregnancy) on the neonatal development and maternal organ wts of Long Evans rats was studied. DMBA significantly increased the gestation period from 19.3 to 23.9 days. It decreased the wts of pups weighed on days 6, 11, 17, and 28 after birth, the decrease being significant in the case of the 6- and 28-day-old pups. DMBA also significantly decreased the dry mammary gland wt and heart wt of the dams, but had no significant effects on mammary milk content or liver and kidney wts of the dam. The data indicate that DMBA may have a deleterious effect on the maternal cardiovascular system and that it has an in utero inhibiting effect on the future growth of pups. (8 refs)

- 79-1440** Structural Gene Products of the Murine Ah Locus: Immunochemical Evidence for Two Forms of Liver P-450 Induced by 3-Methylcholanthrene (Meeting Abstract). (Eng) Negishi, M. (NICHD, NIH, Bethesda, MD, 20014); Nebert, D. W. *Fed Proc* 38(3, Part 1): 495; 1979. (no refs)

- 79-1441** The Effect of Two Polychlorinated Biphenyls (Kanechlor 500 and Delor 106) and 3-Methylcholanthrene on the Activity of Some Rat Liver Microsomal Enzymes. (Ger) Butschak, G. (Zentralinstitut für Krebsforschung, Akademie der Wissenschaften, DDR, 1115 Berlin-Buch, E. Germany); Teichmann, B.; Scheunig, G.; Ziebarth, D. *Acta Biol Med Ger* 37(7): 969-977; 1978.

The effects of Kanechlor 500 (500 mg/kg ip), Delor 106 (500 mg/kg ip), and 3-methylcholanthrene (3-MC; 100 mg/kg ip), injected in single doses into 4 to 5-wk-old male Wistar rats, on the enzymatic demethylation of ethylmorphine (EM), dimethylnitrosamine (DMNA), and 4-dimethylaminoazobenzene (DAB) and on the activity of aryl hydrocarbon hydroxylase (AHH) with benzo(a)pyrene as substrate and of azoreductase with DAB as substrate were studied. 3-MC had no effect on the demethylation of EM, and it caused a considerable but insignificant increase in the demethylation of DMNA. However, 3-MC significantly increased the demethylation of DAB by a factor of 2.5. All three demethylation reactions were increased significantly by both polychlorinat-

ed biphenyls (PCB's): Delor 106 caused an increase by a factor of 3-6, and its effect was 20%-30% higher than that of Kanechlor 500. AHH and azoreductase activities were increased by all three inducers more than fourfold compared with the initial activities. The PCB's, especially Delor 106, were more active than 3-MC. The findings indicate that PCB's are suitable for the pretreatment of experimental animals from which enzyme preparations are to be used in the mutagenicity screening of potential carcinogens. (41 refs)

79-1442 Effects of Subcutaneous Administration of Chemical Carcinogens on Leukemia in C58 Mice. (Eng) Whitmire, C. E. (Toxicology Branch, Carcinogenesis Testing Program, Div. Cancer Cause and Prevention NCI, NIH, Bethesda, MD, 20014). *J Natl Cancer Inst* 62(3): 555-559; 1979.

The effects of sc administration of 3-methylcholanthrene (3-MC: 150 or 300 μ g), 7,12-dimethylbenz(a)anthracene (DMBA: 150 or 300 μ g), and benzo(a)pyrene (BP: 150 μ g) on spontaneous viral leukemia and sc sarcoma induction were evaluated in weanling C58/J mice. 3-MC produced significantly more sarcomas at the inoculation site than did DMBA or BP; moreover, it interfered with leukemia development (the incidence was 0% and 5% at 150 and 300 μ g, respectively, vs 33% in controls). DMBA produced fewer sarcomas, and the incidence of leukemia was comparable to that found in controls. BP accelerated the incidence of leukemia (to 52%), although no sarcomas were produced. When the effect of the age of the mice at the time of 3-MC treatment on the incidence of leukemia and sarcomas was studied, newborn and weanling mice were found to develop primarily sarcomas. In contrast, no sarcomas were produced in 16-wk-old mice, and 52%-64% developed leukemia. The reason no sarcomas were found in the C58 mice was apparently different from the reason no sarcomas were found in AKR mice, inasmuch as the AKR mice did not live long enough for sarcomas to develop. Immunologic surveillance may have played a part in the sarcoma suppression in the C58 mouse. (16 refs)

79-1445 Determination of Benzo(a)pyrene and Other Polynuclear Aromatic Hydrocarbons in Air-

borne Particulate Material by Ultrasonic Extraction and Reverse Phase High Pressure Liquid Chromatography. (Eng) Golden, C. (Environmental Sciences Res. Lab., Office Res. and Development, U.S. Environmental Protection Agency, Research Triangle Park, NC, 27711); Sawicki, E. *Anal Lett* 11(12): 1051-1062; 1978.

A procedure for determining benzo(a)pyrene (BP) and other polynuclear aromatic hydrocarbons (PAH) in airborne particulates is described. The method consists of improved ultrasonic extraction of particulates collected on glass fiber filters, reverse-phase high-pressure liquid chromatographic separation, and identification and quantitation of the PAH by fluorescence detection at low picogram levels. Precision and accuracy measurements indicate full recovery of PAH and good extraction reproducibility. The detection limit of BP was < 10 picograms. (13 refs)

79-1446 A Rapid In Vitro Assay for Carcinogenicity of Chemical Substances in Mammalian Cells Utilizing an Attachment-Independence Endpoint. (Eng) Traul, K. A. (Pfizer Inc., Maywood, NJ, 07607); Kachevsky, V.; Wolff, J. S. *Int J Cancer* 23(2): 193-196; 1979.

A technique combining growth over an agar medium base and carcinogen-induced transformation of Rauscher leukemia virus (RLV)-infected rat embryo cells resulted in a new assay that allows both preliminary screening for chemical carcinogenicity and transformation confirmation to be completed in 10 days. The method takes advantage of the range of chemical sensitivity of RLV-infected rat embryo cells, but provides for a readout based on the ability of transformed cells to survive under conditions that select for attachment independence. The target cells, 2FR₄50, were treated for 72 hr with a chemical carcinogen and then plated into Petri dishes containing a solid bottom layer of agar medium. Viable cell counts were made 3 and 6 days later and compared with parallel data from solvent-treated control cells. 2FR₄50 cells treated with any of 10 chemical carcinogens, including such diverse compounds as benzo(a)pyrene, 3-methylcholanthrene, 2-acetylaminofluorene, NiSO₄, and urethane, showed an av increase of 225% in survival over controls. Phenanthrene, a noncarcinogen, induced no increase in survival of 2FR₄50 cells. This assay appears to permit the detection of carcinogens of various chemical classes with a simple test readout within 10 days. (20 refs)

79-1447 Increase in Genetic Activity of the Polycyclic Hydrocarbon Benzo(a)pyrene by Inhibition of the Epoxide Hydrase in an Activation System In Vitro. (Eng) Roszinsky-Kocher, G. (Dept. Human Genetics and Anthropology, Universitatstrasse 1, Geb. 23.12, D-4000 Dusseldorf 1, W. Germany); Rohrborn, G. *Mutat Res* 66(2): 199-203; 1979.

The effect of the epoxide hydrase inhibitor cyclohexene oxide (CO) on the genetic activity of benzo(a)pyrene (BP) was stud-

ied in Chinese hamster ovary (CHO) cells with and without a mouse liver homogenate fraction (S9). Cell cultures treated with BP alone did not show any increase in the sister-chromatid exchange (SCE) frequency. The number of metaphases with structural chromosome aberrations increased only when BP was activated. In the presence of the S9 fraction and CO, BP increased the SCE level from 20.3 to 31.1/metaphase, and it also induced structural chromosomal aberrations. The increase in SCE was dose-dependent, but the induction of chromosome aberrations was not. CO alone and CO + BP, but without the S9 fraction, increased the SCE frequency. Based on these results, which are very different from those obtained with 1,1,1-trichloropropane-2,3-oxide (another epoxide hydrazine inhibitor), the effect of CO on the induction of SCE and chromosome aberrations in a BP-metabolizing system was less than expected. The results suggest that epoxides are not the most mutagenic BP metabolites. (11 refs)

- 79-1448 Stereospecificity of Metabolism of Benzo(a)pyrene (BP) to (\pm)trans-7,8-Dihydroxy-7,8-dihydro-BP by Rat Liver Nuclear Enzymes.** (Eng) Jennette, K. W. (Dept. Chemistry, Dartmouth Coll., Hanover, NH, 03755); Bornstein, W.; Chuang, A. H.; Bresnick, E. *Biochem Pharmacol* 28(2): 338-339; 1979.

The stereospecificity of the formation of (\pm)trans-7,8-dihydroxy-7,8-dihydrobenzo(a)pyrene (BP 7,8-diol) from benzo(a)pyrene(BP) by rat liver nuclear enzymes was determined using male CD rats pretreated with 3-methylcholanthrene (20 mg/kg ip). The animals were killed 24 hr later, their livers excised, and nuclei isolated. The nuclei were incubated with BP for 30 min, and the metabolites formed were identified by high-pressure liquid chromatography. The results indicated that 92% of the BP 7,8-diol formed by rat liver nuclei was the (-) isomer. The production of (-)-BP 7,8-diol is also > 90% with rat liver microsomal enzymes. Therefore, the stereospecificity of the BP-metabolizing enzymes of the two systems is substantially the same. (24 refs)

- 79-1449 Double-Stranded DNA Stereoselectively Binds Benzo(a)pyrene Diol Epoxides.** (Eng) Meehan, T. (Midland Macromolecular Inst., 1910 W. St. Andrews Drive, Midland, MI, 48640); Straub, K. *Nature* 277(5695): 410-412; 1979.

The enantiomers of (\pm) anti-benzo(a)pyrene (BP) diol epoxide were resolved and reacted with calf thymus DNA. Each enantiomer reacted with the exocyclic amino group of deoxyguanosine to form a pair of diastereomers in a ratio that depended on the secondary structure of the nucleic acid. The (+) enantiomer reacted preferentially or asymmetrically with deoxyguanosine in double-stranded DNA, but the two enantiomers reacted equally with the same position in single-stranded DNA. The basis for the stereoselective binding is unknown, but it may involve formation of sterically oriented physical complexes before covalent attachment of the hydrocarbon to DNA. The mode of binding in the deoxyadenosine

sine sites, on the other hand, must be different, in that the (+) and (-) enantiomers reacted equally in either single- or double-stranded DNA. The results suggest that, in addition to metabolic factors, chemical and physical interactions with DNA may be important in evaluating the biological potency of carcinogenic and aromatic hydrocarbons. - 79-1454 Reduction of Benzo(a)pyrene Mutagenicity by Dihydrodiol Dehydrogenase.** (Eng) Glatt, H. R. (Section Biochemical Pharmacology, Inst. Pharmacology, Univ. Mainz, D-6500 Mainz, W. Germany); Vogel, K.; Bentley, P.; Oesch, F. *Nature* 277(5694): 319-320; 1979.

The effect of rat liver dihydrodiol dehydrogenase (DD) on the mutagenicity of benzo(a)pyrene (BP) was studied using the microsome/Salmonella test. When BP was activated by liver microsomes from 3-methylcholanthrene-treated mice, addition of pure DD clearly reduced the mutagenicity. The effect increased with DD dose up to 0.5 unit/plate; further addition of DD had no significant effect. Thus, max reduction of mutagenicity was achieved using about 15-fold more enzyme than that present in the amount of liver equivalent to the microsomes used for activation. The degree of BP mutagenicity that could be removed by DD varied with the bacterial strain: with TA98 it was 30%-60%, whereas with TA1537 it was 15%-25%. DD had no effect on BP mutagenicity when microsomes from untreated control mice

were used. Thus, DD can protect against mutagenic effects of BP, but not all the mutagenic metabolites of BP can be removed by DD. (26 refs)

79-1461 Benzpyrene Metabolism in Human Diploid Fibroblasts. (Eng) Wohler, W. (I. Medizinische Klinik, Universitat Hamburg, Martinistrasse 52, D-2000 Hamburg 20, W. Germany); Bartram, C. R.; Schurer, C. C.; Rudiger, H. W. *Monogr Hum Genet* 10: 165-170; 1978.

Benzo(a)pyrene (BP) metabolism and the formation of DNA adducts in human diploid fibroblasts increased during 6 hr

of incubation and proceeded linearly thereafter. Confluent cells metabolized about 10 times more BP than exponentially growing fibroblasts. BP was predominantly metabolized via cytochrome P-448-dependent monooxygenase. Evidence that epoxide hydratase might be predominantly involved in the generation of reactive diol epoxides is presented. Both BP metabolism and DNA adduct formation exhibited a broad interindividual variability of more than one order of magnitude in fibroblasts from different donors. (15 refs)

79-1462 Metabolism and Formation of DNA Adducts of Benzo(a)pyrene in Human Diploid Fibroblasts. (Eng) Rudiger, H. W. (I. Medizinische Klinik, Univ. Hamburg, Martinistrasse 52, 2000 Hamburg 20, W. Germany); Marxen, J.; Kohl, F. V.; Melderis, H.; Wichert, P. V. *Cancer Res* 39(3): 1083-1088; 1979.

Variations in the formation of water-soluble metabolites and DNA adducts of benzo(a)pyrene (BP) by skin fibroblast cultures were studied using biopsy material from 29 patients with lung cancer, 7 patients with melanoma, and 28 normal controls. Cultured fibroblasts incubated with G-³H-BP yielded about 10 times more water-soluble metabolites and DNA adducts at stationary growth phase than did proliferating cultures. In all instances, BP metabolism was completely inhibited by α -naphthoflavone (ANF). Trichloropropenoxide and cyclohexenoxide, inhibitors of epoxide hydratase, primarily inhibited the formation of DNA adducts; they had relatively little effect on the formation of water-soluble metabolites. BP turnover in 11 cultures from the same individual showed a coefficient of variation of 40%, which was similar to that of cultures from different donors. However, the ratio of metabolism to DNA adducts in different cultures from the same donor showed a coefficient of variation of only 6.6%. The ratio of water-soluble metabolites to DNA adducts was significantly decreased in cultures derived from lung cancer patients, compared with those derived from melanoma patients or healthy controls. BP metabolism and the formation of DNA adducts in control fibroblasts were correlated with the age of the proband. (44 refs)

79-1465 Ultramicro Analysis of Benzo(a)pyrene in Food. (Eng) Yamaguchi, K. (Faculty Pharmaceutical

Sciences, Univ. Tokyo, Hongo, Tokyo, Japan). *Chem Pharm Bull (Tokyo)* 26(11): 3600-3602; 1978.

The analysis of benzo(a)pyrene (BP) in food by mass-fragmentography (specific ion monitoring by gas chromatography-mass spectrometry) is described. A short (5-10 cm) alkali column at the injection port traps background contaminants, and a column containing the liquid crystal N,N'-[p-butoxybenzyliden]- α,α' -bi-p-toluidine is used to separate BP from benzo(e)pyrene. Two procedures for extracting BP from food with this method are described. (6 refs)

79-1466 Environmental Mutagens in Urban Air Particulates. (Eng) Commoner, B. (Center Biology Natural Systems, Washington Univ., St. Louis, MO, 63130); Madyastha, P.; Bronsdon, A.; Vithayathil, A. J. *J Toxicol Environ Health* 4(1): 59-77; 1978.

The feasibility of using the *Salmonella typhimurium* mutagenesis assay to detect carcinogens in the urban environment was tested by analyzing Chicago air particulates. Extracts of air filter samples were assayed for mutagenicity to *Salmonella* strain TA1538 with and without microsomes prepared from Aroclor-induced rat livers. The extracts contained mutagenicity with and without microsomal activation. Dose-response curves were obtained with extracts of 15 successive samples taken during 1975. The presence of several mutagenic constituents was demonstrated by thin-layer chromatography of particularly active samples, in which the active material was located by mutagenic analysis of successive chromatographic zones. Mass spectrometric analysis of material isolated from an original air filter sample indicated that benzo(a)pyrene and benzo(e)pyrene were present. It is concluded that screening techniques based on the *Salmonella* mutagenicity assay are suitable for analyzing the environmental distribution of organic carcinogens associated with urban air particulates. 79-1467 Methylcobalamin Methylation of Chloroplatinide: Bound Chloride, Valence State, and Relative Mutagenicity. (Eng) Taylor, R. T. (Biomedical Sciences Div., Lawrence Livermore Lab., Univ. California, Livermore, CA, 94550); Happe, J. A.; Wu, R. *J Environ Sci Health A* 13(9): 707-723; 1978.

A methyl-Pt compound formed by incubating K_2PtCl_6 with methylcobalamin (MeB-12) is further characterized physicochemically, and its mutagenicity was compared with that of K_2PtCl_6 and K_2PtCl_4 in auxotrophic Chinese hamster ovary cells (CHO AUXB1). The complexed chloride was determined from nuclear magnetic resonance spectra of the ^{35}Cl -displaced by competing thiocyanate (SCN^-) anions. Release of three chlorides per Pt combined with a Me/Pt ratio of 1.0 indicated a metal coordination number of 4. This is in agreement with x-ray photoelectron spectra, which show that most of the Me-Pt product contains Pt in the +2 valence state. Based on these data and the anionic nature of the product

at pH's from 2.5-7.5, the product is represented as $MePtCl_3^{2-}$. In comparison to the closely related complexes K_2PtCl_6 and K_2PtCl_4 , $MePtCl_3^{2-}$ was slightly less cytotoxic to CHO AUXB1 cells. At concentrations of 15-70 μM , all three compounds induced a 6 to 10-fold increase in the frequency of CHO AUXB1 revertants. Revertants arising either spontaneously (frequency approx 5×10^{-7}) or induced with chloroplatinates or 4-nitroquinoline N-oxide (4-NQO) regained a permanent capacity to grow in medium lacking glycine + adenosine + thymidine. In contrast to the corresponding chloroplatinates, K_2PdCl_4 and K_2PdCl_6 were not mutagenic in CHO AUXB1 as inducers of reversion to prototrophy. They were also 5-10 time less cytotoxic. (13 refs)

79-1468 Disposition of N-(4-Hydroxyphenyl)-All-trans-retinamide in Rats (Meeting Abstract). (Eng) Swanson, B. N. (NIH, Bethesda, MD, 20014); Zaharevitz, D. W.; Frolik, C. A.; Sporn, M. B. *Fed Proc* 38(3, part 1): 265; 1979. (no refs)

79-1469 Species Differences in the Substrate Specificity of Hepatic Cytochrome P-448 from Polycyclic Hydrocarbon-treated Animals. (Eng) Thorgerisson, S. S. (Lab. Chemical Pharmacology, NCI, NIH, Bethesda, MD, 20014); Atlas, S. A.; Boobis, A. R.; Felton, J. S. *Biochem Pharmacol* 28(2): 217-226; 1979.

An attempt was made to determine whether the pattern of α -naphthoflavone (NF) inhibition of selected monooxygenase activities associated with aromatic hydrocarbon responsiveness in the mouse could be used to differentiate among the various forms of cytochrome P-448 in mice, rats, hamsters, guinea pigs, and rabbits. The in vitro effects of NF on aryl hydrocarbon hydroxylase (AAH), 2-acetylaminofluorene N-hydroxylase (AAFH), biphenyl 2-hydroxylase (B2H), and biphenyl 4-hydroxylase (B4H) activities were investigated before and after methylcholanthrene (MC) treatment of C57BL/6N and DBA/2N mice, Sprague-Dawley rats, Syrian hamsters, guinea pigs, and New Zealand white rabbits (all males). The electrophoretic pattern of cytochrome P-450 subunits and the reduced CO-hemoprotein difference spectra of the microsomal fractions were also studied. Pretreatment of animals with MC caused: (1) a 1.5- to 2-mm hypsochromic shift in the Soret peak of the reduced hemoprotein-CO complexes in liver microsomes from C57BL/6N mice, rats, hamsters, and rabbits; a 0.5-nanometer hypsochromic shift in guinea pigs and no shift in DBA/2N mice; and (2) an increase in cytochrome P-450 apoproteins of the following mol wts upon sodium dodecyl sulfate-polyacrylamide gel electrophoresis: 54,000 (54K) and 55K in C57BL/6N mice; 48K, 54K, and 55K in rats; 49K and 54K in hamsters; and 54K and 57K in rabbits. A small increase in the 54K band was seen in DBA/2N mice and no increase was seen in guinea pigs. In vitro addition of α -NF selectively inhibited all four monooxygenase activities in MC-treated C57BL/6N mice, rats, and hamsters; 2-AAFH and B4H activities in rabbits; and AAH, AAFH, and B4H activities in guinea pigs. NF

enhanced AAH and B2H activities in liver microsomes from both control and MC-treated rabbits, but only B2H activity in guinea pigs. AAFH activity was increased in both control and MC-treated DBA/2M mice, but only in control C57BL/6N mice. These data indicate that hepatic cytochrome P-448 is composed of multiple cytochromes that differ among animal species, each catalyzing different monooxygenase activities. (35 refs)

79-1470 The Effect of Isolation Stress on Some Carcinogen-Metabolising Enzyme Systems of Rats.

(Eng) Capel, I. D. (Res. Dept., Marie Curie Memorial Foundation, The Chart, Oxted, Surrey RH8 0TL, England); Williams, D. C. *IRCS Med Sci (Cancer)* 7(1): 14; 1979.

In male Sprague-Dawley rats, isolation stress (ie, isolation in darkened boxes for 2-8 days) increased the activity of enzymes responsible for the metabolic activation of carcinogens but did not affect their excretion. This treatment increased plasma cortisol levels and aryl hydrocarbon hydroxylase activity, but it did not affect uridine diphosphoglucuronic acid transferase levels. (5 refs)

79-1471 Dietary Protein, Aryl Hydrocarbon Hydroxylase and Chemical Carcinogenesis in Rats. (Eng)

Clinton, S. K. (Sch. Basic Medical Sciences, Univ. Illinois, Urbana, IL, 61801); Truex, C. R.; Visek, W. J. *J Nutr* 109(1): 55-62; 1979.

The relationships between dietary protein concentration (7.5%, 15%, or 45%) to changes in hepatic aryl hydrocarbon hydroxylase (AHH) activity and 7,12-dimethylbenz(a)anthracene (DMBA, 2 mg/g in a single po dose) mammary carcinogenesis were studied in female Sprague-Dawley rats. The specific activity and activity per gram of body wt of AHH, cytochrome P-450, and NADPH cytochrome c reductase increased as the percentage of protein in the diet increased. The incidence of palpable mammary tumors in DMBA-treated rats was inversely related to the dietary protein concentration prior to carcinogen treatment, being 75% in the 7.5% protein group, 44% in the 15% group, and 25% in the 45% group at 25 wk. The period between DMBA administration and detection of palpable tumors, the percentage of tumor-bearing rats with multiple tumors, and the number of tumors per tumor-bearing rat were also inversely related to dietary protein concentration. Dietary protein concentration following DMBA treatment had no significant effect on tumor incidence or latency. The results support the hypothesis that increasing dietary protein may decrease the concentration of potential carcinogenic DMBA metabolites reaching the mammary gland by stimulating the hepatic metabolism of DMBA. (46 refs)

79-1472 Aryl Hydrocarbon (Benzo[a]pyrene) Hydroxylase Development in Rat Mammary Tissue.

(Eng) Fysh, J. M. (Dept. Biology, Univ. Windsor, Windsor,

Ontario, Canada N9B 3P4); Okey, A. B. *Biochem Pharmacol* 27(24): 2968-2972; 1978.

The ontogeny of aryl hydrocarbon hydroxylase (AHH), its inducibility by β -naphthoflavone (BNF: 80 mg/kg, ip, for 2 days prior to sacrifice at ages 22-444 days), and its inhibition by α -naphthoflavone (ANF: 10 μ M) were studied in female Sprague-Dawley rats. An attempt was made to determine the capacity of mammary tissue to metabolize benzo(a)pyrene (BP) and to determine whether age-related variations in mammary AHH activity are related to susceptibility to polycyclic aromatic hydrocarbon (PAH)-induced carcinogenesis. In control rats, AHH activity was high at ages 28-35 days, but it decreased to lower levels by 42 days. Addition of ANF to the microsomal incubation mixture produced an approx 35% inhibition of basal AHH activity. Ovariectomy of control rats produced a twofold increase in AHH activity but had no effect on induction of AHH by BNF. Phenobarbital pretreatment (80 mg/kg/day for 3 days, ip) only slightly increased mammary AHH activity. The ratio of BNF-induced activity:control activity varied with the age of the rats, ranging from 6- to 70-fold for mammary tissue and 11- to 36-fold for liver tissue. ANF inhibited BNF-induced AHH activity by about 60%, especially at ages when inducibility was highest (91-262 days). The data suggest that no simple relationship exists between mammary or liver AHH activity and age-related differential sensitivity to carcinogenesis by PAH. (16 refs)

79-1473 Epoxide Hydrase and Mixed-Function Oxidase Activities of Rat Liver Nuclear Membranes.

(Eng) Mukhtar, H. (Lab. Pharmacology, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Elmamlouk, T. H.; Bend, J. R. *Arch Biochem Biophys* 192(1): 10-21; 1979.

The specific cytochrome P-450 levels and aryl hydrocarbon hydroxylase (AHH), aminopyrine N-demethylase, benzphetamine N-demethylase, NADPH-cytochrome c reductase, and epoxide hydrase activities were compared in hepatic microsomes, nuclei, and nuclear membranes prepared from male Sprague-Dawley rats. Nuclear activity ranged from 1.8% (for NADPH-cytochrome c reductase) to 11.3% (for AHH) of the microsomal activity. The specific activity of the various parameters measured in nuclear membranes ranged from 1.3-fold (for cytochrome P-450) to 10.2-fold (for NADPH-cytochrome c reductase) greater than that in intact nuclei. Nuclear and microsomal epoxide hydrases were both induced by phenobarbital but not by 3-methylcholanthrene. Nuclear membrane and microsomal epoxide hydrase were both inhibited to a similar degree by 1,1,1-trichloropropene oxide, cyclohexene oxide, and trans-stilbene oxide. The apparent K_m value for nuclear membrane epoxide hydrase was 20 μ M for benzo(a)pyrene 4,5-oxide, which is 5.5-fold lower than the corresponding microsomal K_m value (112 μ M). Epoxide hydrase in intact nuclei from various organs was in the following order: kidney > lung > spleen or heart. Increases of 2.2- and 2.5-fold in specific hydrase activity were

detected in kidney and lung when nuclear membranes were compared with intact nuclei. The presence of significant monooxygenase and epoxide hydrase activities in the nucleus is consistent with a role in the bioactivation of environmental pollutants to carcinogenic and/or mutagenic products. (47 refs)

- 79-1474 The Role of Diethylstilbestrol Metabolism in Its Binding to Fetal and Maternal Tissues (Meeting Abstract).** (Eng) Miller, R. K. (Dept. Obstetrics, Univ. Rochester, Rochester, NY); McKenzie, R. C. *Fed Proc* 38(3, part 1): 438; 1979. (1 ref)

- 79-1475 Activity of Aryl Hydrocarbon Hydroxylase in Psoriatic Skin.** (Eng) Chapman, P. H. (Dept. Pharmacological Sciences, Wolfson Unit, Claremont Place, Univ. Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, England); Rawlins, M. D.; Shuster, S. *Lancet* 1(8111): 297-298; 1979.

The activity of aryl hydrocarbon hydroxylase (AHH) in the normal and psoriatic epidermis from 20 patients with psoriasis was compared with that in epidermis from 13 normal subjects using benzo(a)pyrene as substrate. Induction of epidermal AHH activity by benzantracene (BA) was also measured. In the absence of BA, AHH activity was significantly lower in epidermis from psoriatic lesions [1.84 picomoles (pmol) 3-hydroxybenzo(a)pyrene/mg protein/hr] and normal epidermis from psoriasis patients (2.41 pmol) than in epidermis from normal subjects (3.41 pmol). Preincubation with 100 micromoles/liter of BA significantly increased the absolute activity of AHH in epidermis from normal subjects and increased it significantly but to a lesser extent in the uninvolved epidermis of psoriatic patients. The epidermis from psoriatic lesions showed no induction of AHH in response to BA. The enzyme defect in the psoriasis patients may be related to the primary genetic abnormality of the disease. Since AHH activity is a major factor in chemical carcinogenesis, the risk of skin cancer, and perhaps cancers of other organs, may be reduced in individuals with psoriasis. (4 refs)

- 79-1476 High-Pressure, Reverse-Phase Partition Chromatography Separation of Diethylstilbestrol Metabolites and Analogs.** (Eng) Gottschlich, R. (Inst. Toxicology, Univ. Wurzburg, Versbacher Landstrasse 9, D-8700 Wurzburg, W. Germany); Metzler, M. *Anal Biochem* 92(1): 199-202; 1979.

Various conjugated and oxidative metabolites of diethylstilbestrol (DES) were separated by high-pressure, reverse-phase liquid chromatography on C_8 - and C_{18} -hydrocarbon phases with water-methanol gradients. The compounds separated included metabolites such as 4'-hydroxy-propiophenone, 3'-hydroxy-DES, β -dienestrol, and ω -hydroxy- β -dienestrol. (10 refs)

- 79-1477 Species and Organ Specificity of the trans-Stilbene Oxide Induced Effects on Epoxide Hydratase and Benzo(a)pyrene Monooxygenase Activity in Rodents.** (Eng) Oesch, F. (Section Biochemical Pharmacology, Inst. Pharmacology, Univ. Mainz, Obere Zahlbacher Strasse 67, D-6500 Mainz, W. Germany); Schmassmann, H. *Biochem Pharmacol* 28(2): 171-176; 1979.

The effect of trans-stilbene oxide (TSC) on epoxide hydratase (EH) and benzo(a)pyrene monooxygenase (BPMO) activity was investigated in the liver, kidney, lung, skin, and testis of rats, mice, and hamsters. Adult male and female Sprague-Dawley rats, male Syrian Golden hamsters, and male NMRI mice were treated with 0.2, 0.5, or 2.0 millimoles (mmol)/kg ip 1x/day for 3 days. The animals were killed 24 hr later and the microsomal enzyme activities determined. The ability of TSO to induce liver EH activity, expressed as percent of controls, was 350%, 180%, and 140% in the rat, mouse, and hamster, respectively. In the rat livers, EH activity was induced to 300%-400% of controls after treatment with 2.0 mmol TSO, but BPMO activity was not affected. Selective induction of EH was also found in hamster liver but not in mouse liver, in which BPMO activity was induced to about the same extent as EH activity. The only extrahepatic organ in which EH activity was increased after TSO treatment was the rat kidney, but the extent of induction was lower than that in the liver. Topical and sc treatment with TSO for 10 and 12 days, respectively, decreased EH activity in rat skin to 70% of that found in control animals. Thus, applicability of TSO to investigations of the role of EH in the metabolism of polycyclic hydrocarbons is limited to systems in which rat liver can be used. (33 refs)

- 79-1478 Variability of Response to Diethylstilbestrol: A Comparison of Inbred with Hybrid Mice.** (Eng) Greenman, D. L. (Div. Molecular Biology, Natl. Center Toxicological Res., Jefferson, AR, 72079); Delongchamp, R. R.; Highman, B. *J Toxicol Environ Health* 5(1): 131-143; 1979.

The uterine and thymic wt responses to diethylstilbestrol (DES) were examined in BALB/cStCrIFC3Hf/Nctr, C57BL/6JfC3Hf/Nctr, [C57BL/6 x BALB/c]F₁ hybrid (F₁), and monohybrid cross offspring (F₂) from the breeding of F₁ mice. Approx 400 weanling females from each genetic population were exposed for 6 days to DES (2.5-1,000 ppb in the diet). Uterine wt variances for the BALB/c and F₁ mice were indistinguishable from each other and significantly smaller than variances for the F₂ and C57BL/6 mice. Thymic wt variances were also smallest for BALB/c and F₁ mice and highest for C57BL/6 mice. In a chronic feeding study, body wt responses were examined and gross necropsy observations were recorded for the pituitaries and testes of 576 mice of each genetic population given 5-640 ppb DES. The dose-response effect on body wt was examined at 30 wk in males and 60 wk in females. Variances were smallest for BALB/c mice and largest for F₂ hybrids. Those for F₁ and C57BL/6 mice were intermediate and indistinguishable from each other. Gross necropsy of animals dead or moribund dur-

ing the first 15 mo of DES exposure indicated the following: (1) at 15 mo, pituitary and testicular responses were visible only at ≥ 160 ppb DES; (2) BALB/c males developed mainly testicular lesions but C57BL/6 mice developed pituitary lesions; and (3) F₁ and F₂ animals developed both types of lesions and were not different from each other in this respect. It is concluded that generalizations cannot be used in selecting the best experimental animal for a specific purpose. (12 refs)

79-1479 Influence of Diethylstilbestrol Treatment on Prolactin Cells of Female ACI and Sprague-Dawley Rats. (Eng) Holtzman, S. (Medical Dept., Brookhaven Natl. Lab., Upton, NY, 11973); Stone, J. P.; Shellabarger, C. J. *Cancer Res* 39(3): 779-784; 1979.

Pellets containing 5 mg diethylstilbestrol (DES) and 15 mg cholesterol were implanted in female ACI and Sprague-Dawley (S-D) rats for periods ranging from 2 to 214 days. In view of the differences between these two strains in mammary tumorigenesis, plasma prolactin (PL) levels, and gross pituitary (Pt) responses, the cytology of Pt glands that were fixed during the course of this study was examined and an immunohistochemical evaluation was made of their PL cell responses. Although plasma PL levels were elevated in both strains by 2 days after implantation, during the first 10 days of treatment there were no significant increases in Pt wt in both strains. Pt glands from animals of both strains killed on day 10 exhibited enlarged anti-rat PL-binding cells. By day 28, the Pt glands of DES-treated ACI rats were significantly enlarged, and a hypertrophic and hyperplastic response of their PL cells was detected. From day 56 to the end of the experiment, gross Pt tumorigenesis was evident in the ACI but not in the S-D rats. At the microscopic level, adenomatous lesions involving PL cell hyperplasia were observed in both strains. S-D and ACI rats exhibited multiple centers of marked vascularization predominated by granular acidophilic cells. These centers were more extensive and larger in the Pt's of the ACI rats. Two types of immunoreactive PL cells were observed in lesioned Pt glands of both strains: polyhedral, strongly reactive cells that were hypertrophic and more numerous in the ACI rats; and smaller, weakly reactive cells that were numerous in the adenomatous areas of the glands in both strains. It was concluded that the lesions in ACI and S-D females represented different quantitative responses of their PL cells to DES treatment. (20 refs)

79-1480 Neoplastic Responses and Correlated Plasma Prolactin Levels in Diethylstilbestrol-treated ACI and Sprague-Dawley Rats. (Eng) Stone, J. P. (Medical Dept., Brookhaven Natl. Lab., Upton, NY, 11973); Holtzman, S.; Shellabarger, C. J. *Cancer Res* 39(3): 773-778; 1979.

The relationships between estrogen treatment, prolactin (PL) levels, mammary (Ma) development, and neoplasia induction in the Ma tissue and pituitary (Pt) glands of female Sprague-Dawley (S-D) and ACI rats were investigated. Pellets

containing 5 mg diethylstilbestrol (DES) and 15 mg cholesterol were implanted sc in 84-day-old rats. [G-³H]DES (32.9 nanocuries/mg DES) was incorporated into each pellet. Animals were decapitated, blood was collected at various times after implantation, and the amount of [G-³H]DES remaining in each pellet was determined. Plasma PL levels were determined by radioimmunoassay. DES was released from the pellets exponentially, and the release was not significantly different in S-D rats than in ACI rats. No Ma tumors developed in any treated or untreated S-D rats. In contrast, 90% of the treated ACI rats had developed two or more Ma adenocarcinomas by 130 days, and by 214 days, 90% had four or more Ma adenocarcinomas. Pt wt increased significantly in treated ACI rats by 28 days. By day 130, the Pt's were 2-7 times as heavy as those of controls, and plasma PL levels were 10-40 times higher than those in controls. In contrast, the Pt's of treated S-D rats did not increase significantly in wt, and plasma PL levels were only three to five times higher than of those controls. As early as day 10, the uteri of treated S-D rats were significantly heavier than those of controls, and they contained large amounts of fluid. This effect was not seen in ACI rats. Although the release of DES from the implanted pellet was essentially the same in ACI and S-D rats, three distinctive strain differences in response to DES were noted: Ma adenocarcinomas were found only in ACI rats; Pt PL cell adenomas and associated elevated plasma PL levels were seen only in ACI rats; and pyometritis was induced only in S-D rats. Ma adenocarcinomas and PL cell adenoma responses in the treated ACI rats appear to be correlated with the increasing levels of plasma PL. Thus, prolonged estrogen treatment of ACI and S-D female rats produces distinctly different Ma and Pt neoplastic responses. This disparity in neoplastic responses appears to be reflected in the difference of degree to which the hypophyseal PL cells are stimulated to grow and secrete hormone. (35 refs)

79-1481 Cytological Effects of Diethylstilbestrol (DES) Treatment on the Estrous Cycle of Virgin Long-Evans Female Rats. (Eng) Okediji, O. (Dept. Biology, Atlanta Univ., Atlanta, GA, 30314); Hunter, R. *IRCS Med Sci (Cancer)* 7(1): 28; 1979.

Diethylstilbestrol (DES) treatment (35 mg/2 ml saline/kg body wt by stomach intubation) produced a secondary effect--asynchronous cell proliferation in the vaginal epithelia of virgin Long-Evans rats, leading to prolonged specific stages of the estrous cycle. Two rats remained in persistent estrous for 25 days after treatment, and two others remained in persistent proestrous for 13 days. A further two rats remained in diestrous 13 days after treatment. (6 refs)

79-1482 Transplacental Effect of Diethylstilbestrol in Female Rats. (Eng) Napalkov, N. P. (Petrov Res. Inst. Oncology, 68 Leningradskaya St., Pesochny-2, Leningrad 188646, USSR); Anisimov, V. N. *Cancer Lett* 6(2): 107-114; 1979.

The transplacental effect of diethylstilbestrol propionate (DES; 1 mg/kg sc) was studied in the female offspring of random-bred albino rats exposed sc on gestation day 19. Examination of vaginal smears showed persistent estrus in adult rats treated prenatally with DES. Compensatory ovarian hypertrophy (COH) induced by hemicastration of these rats was not suppressed by estrogens (DES: 0.57 μ g/day x 7, sc). A po test for glucose tolerance revealed decreased utilization of glucose in the offspring of DES-treated rats. Tumors developed in 14/18 progeny transplacentally exposed to DES and 9/34 intact control rats. Tumors of the ovary and the endometrium were found only in the rats treated prenatally with DES; no tumors of the uterine cervix or vagina were observed in either experimental or control groups. It is suggested that transplacental exposure to DES impairs the sex differentiation of the hypothalamus in female rats. The resulting hormonal and metabolic shifts might promote tumorigenesis. 79-1483 Detection of Diethylstilbestrol in the Urine of Calves and Young Cattle by Thin-Layer Chromatography. (Ger) Schellhaas, G. (Landesveterinaruntersuchungsamt für Rheinland-Pfalz, Blucherstrasse 34, 5400 Coblenz, W. Germany); Kleickmann, A.; Nitzschke, E. *Arch Lebensmittelhyg* 29(6): 219-222; 1978.

Three 9- to 10-mo-old calves were treated with diethylstilbestrol (DES) im, and urine samples were analyzed for excreted estrogen by thin-layer chromatography. DES was detected in the urine of a female calf for up to 22 days after the administration of 50 mg and in the urine of two male calves for up to 11 days after the administration of 60 and 70 mg, respectively. 79-1484 Accretion of Biopsy Specimens of Vaginal Adenosis from Patients Exposed In Utero to Diethylstilbestrol, When Transplanted to Athymic Nude Mice. (Eng) Pienkowski, M. M. (Dept. Anatomy, Michigan State Univ., E. Lansing, MI, 48824); Mann, L. C.; Rosloniec, E. F.; Welsch, C. W. *J Natl Cancer Inst* 62(3): 521-523; 1979.

The successful transplantation of biopsy specimens of human vaginal adenosis into female athymic (nude) mice is reported. Biopsy specimens from 10 patients exposed in utero to diethylstilbestrol were transplanted for 30 days into the mice. Almost all grafts were recovered, and they had morphologic features closely resembling those of the original biopsy specimens; ie, cystic, complex, and simple occult glands covered mainly with an endocervical type of epithelium showing extensive squamous metaplasia. Autoradiographic analysis of these grafts after pulse administration of [3 H]thymidine into the mice revealed extensive labeling of epithelial cells. These results imply that female athymic (nude) mice are compatible hosts for accretion of the human adenosis. (24 refs)

79-1485 Effects of Perinatal Testosterone on Mouse Mammary Duct Morphology and Lobule Induc-

tion In Vitro. (Eng) Warner, M. R. (Cancer Res. Lab., Univ. California, Berkeley, CA, 94720). *Cancer Res* 39(3): 744-750; 1979.

The effects of several hormone supplements to the chemically defined medium were assessed in mammary explants from C57BL/Crgl mice that had been inoculated sc with 25 μ g testosterone (TS) on each of the first 5 days of life and in mammary tissues of untreated controls. Tissues were organ-cultured in the fourth week of life after 4, 6, and 9 days of pretreatment with 1 μ g 17 β -estradiol (ED) + 1 mg progesterone (PG). Alveolar and lobular development were similar in tissues of perinatally TS-injected (TS-I) mice and their controls after in vivo pretreatment and after 4 or 9 days of pretreatment followed by culture in all media tested. Both alveolar and lobular development were inhibited in tissues from TS-I mice after 6 days of pretreatment followed by culture with optimal medium for lobular differentiation (ED, PG, aldosterone, growth hormone, prolactin, insulin, and thyroxine). After 6 days of pretreatment, explants from TS-I mice responded similarly to controls after culture with suboptimal media (insulin and thyroxine, or estrogen, PG, aldosterone, insulin, and thyroxine). Perinatal injection of TS, a treatment that has been reported to promote mammary tumorigenesis, did not promote in vitro differentiation of mammary lobules; indeed, significant inhibition of lobule formation was noted after 6 days of pretreatment. A 6-day minimal threshold effect for expression of pretreatment may be involved. Duct diameter increased in explants from TS-I mice after culture in several medium and pretreatment groups. Differences in duct responses were markedly uniform throughout the explant in cultured tissues of TS-I mice. In view of the fact that mammary ducts have been implicated as sites of origin of preneoplastic and neoplastic change, duct responses are of particular interest in relation to subsequent promotion by various endogenous and exogenous factors of the neoplastic potential of mammary tissues of perinatally TS-I mice. 79-1486 Inhibition of Spontaneous Breast Cancer Formation in Female C3H (A ν y/a) Mice by Long-Term Treatment with Dehydroepiandrosterone. (Eng) Schwartz, A. G. (Fels Res. Inst., Temple Univ. Medical Sch., Philadelphia, PA, 19140). *Cancer Res* 39(3): 1129-1132; 1979.

The effects of long-term treatment of 24 weanling female 3CH (A ν y/a) mice with dehydroepiandrosterone (DHEA: 450 mg/kg in sesame oil 3x/wk by po intubation) on spontaneous breast cancer formation was investigated. The 26 control mice received vehicle only. All mice were weighed and palpated for breast cancer weekly. Food consumption was also monitored. The wt gain of the DHEA-treated mice was significantly lower than that of controls at all times after 9 wk of age, even though the cumulative food consumptions of the two groups were not significantly different. Substantial inhibition of mammary gland glucose-6-phosphate dehydrogenase activity was observed at 3, 6, and 24 hr after

DHEA treatment. As of 9 mo of age, the cumulative breast cancer incidence was 0/24 treated mice vs 14/26 controls. These results may be related to the clinical findings of subnormal mean plasma levels of DHEA sulfate in preoperative and postoperative early breast cancer patients as well as in those with advanced disease. 79-1487 Suppression of Pregnancy and Estrogen-Progesterone Induced Mammary Tumorigenesis in Female GR Mice by Chronic Inhibition of Prolactin Secretion (Meeting Abstract). (Eng) Goodrich-Smith, M. A. (Dept. Anatomy, Michigan State Univ., East Lansing, MI, 48824); Brown, C. K.; Welsch, C.W. *Fed Proc* 38(3, part 2): 1256; 1979. (no refs)

79-1488 Attempts to Induce Gonadotropic Tumors (GtT); Immunohistochemical Observations on the Pituitaries of Long Term Gonadectomized Rats (Meeting Abstract). (Eng) Kaul, D. K. (Coll. Physicians and Surgeons Columbia Univ., New York, NY, 10032); Furth, J. *Fed Proc* 38(3, part 1): 1025; 1979. (no refs)

79-1489 Action of Local Progesterone on Benign Breast Disease (500 Case Studies). (Fre) Lafaye, C. (Service des Methodes Physiques, Centre Jean Perrin, Place Henri Dunant, B.P. 392, 63011 Clermont Ferrand Cedex, France); Aubert, B. *J Gynecol Obstet Biol Reprod (Paris)* 7(6): 1123-1139; 1978.

The effect of progesterone treatment was studied in 250 women with mastodynia, 190 women with mastodynia associated with benign pathological changes, and 60 women with painless, benign, pathological changes in the breast. Progesterone was administered topically, daily for 3 mo. Thermography was carried out in each patient before and after treatment. After treatment, the symptoms disappeared completely in 70% of the patients with isolated mastodynia, and the clinical condition improved in an additional 15%. The thermographic features, which were abnormal in these patients before treatment, were normal in 78% of cases and were improved in an additional 19%. Thus, the clinical results were considered excellent or good in a total of 85% of the patients with isolated mastodynia, and the thermographic results were con-

sidered excellent or good in a total of 97%. The thermogram was normal following treatment in 70% of the patients with mastodynia associated with breast disease, and the clinical condition returned to normal in 50%. The clinical condition improved in a further 17%, and thermographic improvement was observed in a further 19%. In patients with breast disease without mastodynia, clinical and thermographic improvement was seen in 10% and 20%, respectively, after progesterone treatment. The results demonstrate that progesterone treatment is useful in the treatment of benign breast conditions. (40 refs)

PHYSICAL CARCINOGENESIS

- 79-1490 Induction of Mouse Epidermal Ornithine Decarboxylase Activity and DNA Synthesis by Ultraviolet Light.** (Eng) Verma, A. K. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Lowe, N. J.; Boutwell, R. K. *Cancer Res* 39(3): 1035-1040; 1979.

Changes in epidermal ornithine decarboxylase (ODC) activity were investigated following exposure of female hairless mice (HKH/Hr) to UV radiation. Irradiation of the mice with UV light of mainly the sunburn region [region of UV light with a wavelength of 290-320 nanometers (UVB)] resulted in a dramatic increase in epidermal ODC activity. A significant increase in enzyme activity was observed as early as 2 hr following UVB exposure. Max activity, about 250- to 350-fold above basal level, occurred at about 28 hr. ODC activity declined steadily thereafter, but it had not returned to the original level even at 48 hr after UVB irradiation. UVB treatment also led to an increased activity of S-adenosyl-L-methionine decarboxylase, a second enzyme in the pathway of polyamine biosynthesis. Enzyme activity was increased at about 6 hr and remained elevated at 48 hr after exposure to UVB. UVB-induced epidermal ODC activity was depressed by treatment of mice with cycloheximide, an inhibitor of protein synthesis, or with 5-azacytidine, an inhibitor of RNA synthesis. The half-life of UVB-induced ODC was found to be about 24 min, as determined by the decline of enzyme activity after cycloheximide treatment. Incorporation of tritiated thymidine into epidermal DNA was initially depressed, and a four-fold increase at 48 hr after UVB exposure was observed. Histological examination of UVB-treated skin revealed epidermal thickening by 48 hr. These studies show that irradiation with UVB, the most carcinogenic region of UV light, induces mouse epidermal ODC activity, and that the elevated enzyme activity precedes increased epidermal DNA synthesis. (26 refs)

- 79-1491 DNA Damage in Synchronized HeLa Cells Irradiated with Ultraviolet.** (Eng) Downes, C. S. (Dept. Zoology, Univ. Cambridge, CB2 3EJ Cambridge, England); Collins, A. R.; Johnson, R. T. *Biophys J* 25(1): 129-150; 1979.

The lethal effect of UV radiation on HeLa cells was found to be least in mitosis and greatest in the late G₁ through early S phase. Photochemical damage to HeLa cell DNA also increased from mitosis toward early S. Computer simulations of UV absorption by an idealized HeLa cell at different stages of the cell cycle indicated that UV sensitivity may be a function of chromatin geometry, although survival is not exclusively a function of damage. (77 refs)

- 79-1492 UV Irradiation Stimulates Synthesis of Poly(adenosine Diphosphoribose) in Associa-**

tion with DNA Repair (Meeting Abstract). (Eng) Berger, N. A. (Jewish Hosp., St. Louis, MO, 63110); Sikorski, G. W.; Petzold, S. J.; Kurohara, K. K. *Fed Proc* 38(3, part 1): 619; 1979. (no refs)

- 79-1493 Repair of Ultraviolet Radiation- and N-Acetoxy-2-acetylaminofluorene-induced DNA Damage in Permeabilized Human Cells (Meeting Abstract).** (Eng) Roberts, J. D. (Washington Univ. Sch. Medicine, St. Louis, MO, 63110); Lieberman, M. W. *Fed Proc* 38(3, part 2): 1404; 1979. (no refs)

- 79-1494 Effects of DNA Damaging Agents on Cultured Fibroblasts Derived from Patients with Cockayne Syndrome.** (Eng) Wade, M. H. (Medical Biological Labs. T.N.O., Lange Kleiweg 139, P.O. Box 45, 2280 AA Rijswijk [Z.H.], Netherlands); Chu, E. H. *Mutat Res* 59 (1): 49-60; 1979.

The cytotoxicity of various physical and chemical agents in skin fibroblast cultures derived from 10 patients with Cockayne's syndrome (CS), 4 parents of CS patients, 2 patients with xeroderma pigmentosum (XP), and 2 normal subjects was studied. The CS cell strains were significantly more sensitive to UV light than the normal cells, with the strains derived from the CS parents being intermediate in UV sensitivity. Caffeine (0.5 mM) had no effect on the UV sensitivity of normal or CS cells, but it increased the UV sensitivity of XP cells. DNA repair synthesis following UV irradiation was similar in normal and CS cells, but it decreased in XP cells. The colony-forming ability of CS and XP cells exposed to N-acetoxy-2-acetylaminofluorene or 4-nitroquinoline-1-oxide differed significantly from that of normal cells, whereas ethyl methanesulfonate and 2-methoxy-6-chloro-9-[3-(ethyl-2-chloroethyl)aminopropylamino]acridine dihydrochloride had similar effects on the colony-forming abilities of CS, XP, and normal cells. The data suggest that excision repair is deficient in patients with CS. (33 refs)

- 79-1495 Excision Repair in Ataxia Telangiectasia, Fanconi's Anemia, Cockayne Syndrome, and Bloom's Syndrome after Treatment with Ultraviolet Radiation and N-Acetoxy-2-acetylaminofluorene.** (Eng) Ahmed, F. E. (Dept. Biology, Brookhaven Natl. Lab., Upton, NY, 11973); Setlow, R. B. *Biochim Biophys Acta* 521(2): 805-817; 1978.

Excision repair of damage due to UV radiation and/or N-acetoxy-2-acetylaminofluorene (AAF) was studied in normal human fibroblasts and various cells from cancer-prone patients with ataxia telangiectasia, Fanconi's anemia, Cock-

ayne's syndrome, or Bloom's syndrome. Measurements were made of unscheduled DNA synthesis, photolysis of bromodeoxyuridine incorporated into parental DNA during repair, and loss of sites sensitive to UV endonuclease. The results indicated that all cell lines were equally proficient in repair of damage caused by UV irradiation and/or AAF. All cell lines showed an additive effect for the combined treatment, and there was quantitative equivalence between UV and AAF as far as the level of repair was concerned. The data indicated that the rate-limiting step in excision repair of UV and AAF damage is different and that there are different enzyme(s) working on the incision of both types of damage. (37 refs)

79-1496 Biochemical Analysis of the Response of Mammalian Cells to UV Light and Sunscreen Agents (Meeting Abstract). (Eng) Long, S. D. (Harvard Sch. Public Health, Boston, MA, 02115); Little, J. B. *Fed Proc* 38 (3, part 1): 846; 1979. (no refs)

79-1497 Some Effects of the Variation of Atmospheric Particulates on Disease in Great Britain. (Eng) Leach, J. F. (Weybridge-Bristol Div., British Aerospace, Filton, Bristol, England); Beadle, P. C.; Pingstone, A. R.; Aughton, P. *Aviat Space Environ Med* 50(1): 72-79; 1979.

The possible UV radiation changes that might have followed from the reduced particulate concentration resulting from the UK Clean Air Acts of 1965 and 1968 are considered by making assumptions as to the nature of the aerosols in the Bristol, England, area and calculating their extinction coefficients. These calculations indicate that both carcinogenic and calciferogenic UV radiation could have increased by an amount approx equivalent to a 10% decrease in the total ozone column. The effect of these radiation changes is detectable in the increased mortality from epitheliomas in the Bristol area and the decrease in femoral neck fracture in England and Wales. Extrapolating these findings to a highly polluted environment, such as that in Los Angeles, suggests that implementation of the US Air Quality Act and Clean Air Amendments of 1970 must result in a significant increase in epitheliomas in the Los Angeles area without compensation from a reduced incidence of vitamin D deficiency disease. (21 refs)

79-1498 Sunlight and Incidence of Cutaneous Malignant Melanoma. Effect of Latitude and Domicile in Sweden. (Eng) Eklund, G. (Dept. Statistics, Univ. Stockholm, Stockholm, Sweden); Malec, E. *Scand J Plast Reconstr Surg* 12(3): 231-241; 1978.

To determine the relationship between exposure to sunlight and the development of cutaneous malignant melanoma (CMM), habitation patterns were investigated for 3,289 CMM patients who were registered between 1959 and 1968 in the Swedish Cancer Registry. The correlation coefficient between latitude and CMM incidence was -0.74, implying

that incidence decreases with increasing latitude and supporting the hypothesis that UV radiation is the predominant cause of melanoma. However, considerable deviations from the regression line were noted in some regions. In addition, analysis of the incidence per 100,000 inhabitants showed that CMM was more prevalent in urban than in rural populations (4.8 in urban men and 5.2 in urban women vs 3.2 and 3.8 in rural men and women, respectively). Thus, CMM incidence increased with population density, a finding that does not agree with the UV radiation hypothesis. Since these discrepancies might be explained by the fact that foreign travel (ie, sunshine trips) among the city dwellers would expose them to more sunlight, a regression analysis of the epidemiological index for UV irradiation and melanoma incidence, adjusted for frequency of foreign travel was carried out. This analysis demonstrated a positive correlation between passport issue frequency, regional latitude, and melanoma incidence (coefficient of 0.83). There was good agreement between the slope of the regression line for latitude and that for the epidemiologic index (coefficient of -0.15). (40 refs)

79-1499 Recommendations of the International Commission of Radiation Protection, 1977. (Fre) Stewart, C. G. (Chalk River Nuclear Labs., Atomic Energy Canada Ltd., Chalk River, Ontario, Canada). *Radioprotection* 13(4): 237-247; 1978.

The 1977 recommendations of the International Commission on Radiation Protection (ICRP) are presented. The cancer risk of ionizing radiation is estimated (in Sieverts per yr) at 2×10^{-3} for the lungs and red marrow, 2.5×10^{-3} for the breast, 4×10^{-3} for the gonads, 5×10^{-4} for the thyroid and bones, and 5×10^{-3} for other tissues. For any organ or any combination of organs, the annual dose should not exceed 5 rem (roentgen-equivalents-man). (16 refs)

79-1500 Double Strand-Breaks and DNA-to-Protein Cross-Links Induced by Fast Neutrons in Bacteriophage DNA. (Eng) Hawkins, R. B. (Dept. Anatomy and Neurobiology, Washington Univ. Sch. Medicine, St. Louis, MO, 63110). *Int J Radiat Biol* 35(1): 1-13; 1979.

Coliphage T7 was suspended in tryptone broth and exposed to a mixture of fast neutrons and gamma radiation. Plaque survival, double-strand breaks, and DNA-protein cross-links were examined. Inactivation of plaque-forming activity appeared to be exponential at the rate of 5.6×10^{-6} inactivation/rad of the mixed neutron-gamma radiation/phage. Thus, the rate of inactivation from neutrons was calculated to be 3.5×10^{-6} /rad of neutron radiation/phage. The pattern of neutral sucrose gradient sedimentation in neutron-gamma-irradiated phage was bimodal, showing an accumulation of small DNA fragments near the top of the gradient with increasing dose. The pattern for phage exposed to gamma radiation alone was not bimodal. Neutrons appeared to cause two types of events in the T7 virion, one involving the deposi-

tion of a large amount of energy in the phage and one involving the deposition of a smaller amount of energy. With the former, 100 or more double-strand breaks were formed per event, whereas with the latter, zero or only a few breaks occurred. Neutron-induced protein-DNA cross-links probably also occur in clusters with enhanced efficiency being relative to low-LET (linear energy transfer) radiation. (17 refs)

- 79-1501 Effect of Destruction of Hypophysis by Radiation on Chemically Induced Mammary Gland Carcinoma in Rats.** (Rus) Savinskaia, A. P. (Cancer Res. Center, Moscow, USSR); Minakova, E. I. *Med Radiol (Mosk)* 24(2): 53-57; 1979.

The effect of radiation-induced destruction of the hypophysis on mammary gland carcinogenesis was studied in 48 albino random-bred rats. Animals received a single po dose of 7,12-dimethylbenz(a)anthracene (DMBA: 20 mg in 0.5 ml of peach oil). Six months later (at this time, all rats were free of mammary gland tumors), 24 rats underwent a single irradiation of the hypophysis with a proton beam (15,000-30,000 rads); 24 rats served as nonirradiated controls. Animals were sacrificed within 5 mo of irradiation, and mammary glands were examined macroscopically and total sagittal sections of the head were examined histologically. Only 1/24 irradiated rats developed a mammary gland adenocarcinoma vs 18% of the nonirradiated rats. There was no association between degree of destruction of the hypophyseal tissue and tumor incidence (the rat with the adenocarcinoma had a completely preserved hypophysis, while another rat with a completely destroyed hypophysis had hyperplasia of the mammary glands). - 79-1502 Secondary Malignant Neoplasms Following Radiotherapy of a Mouse Mammary Carcinoma.** (Eng) Urano, M. (Dept. Radiation Medicine, Massachusetts General Hosp., Boston, MA, 02114); Koike, S.; Ohara, K. *Cancer* 43(1): 151-156; 1979.

The occurrence of secondary malignant neoplasms (SMN's) following radiotherapy of malignant neoplasms was studied using an animal tumor system, and clinical studies of SMN's following radiotherapy of malignant tumors were surveyed. The experimental tumors were third-generation isografts of a mammary carcinoma that arose spontaneously in a C3Hf/He mouse. Application of a single radiation dose ranging from the TCD20 to the TCD98 (radiation dose that yields a 20%-98% probability of local tumor control in 150 days; 5,200, 5,500, 5,900, or 6,300 rads were used) was followed by weekly observations. Most recurrences were observed in the first 150 days, and only a few were seen in the subsequent 150 days. Secondary neoplasms developed frequently following this period, ie, 41/67 animals surviving > 300 days developed secondary neoplasms. They were osteogenic and soft tissue sarcomas, and half the new tumors were found within 490 days after radiotherapy. The results were compared with literature reports of SMN's postoperative ra-

diotherapy for carcinoma of the breast and treatment of retinoblastomas. Most of these secondary human neoplasms were nonepithelial sarcomas. There are a few reports of the occurrence of secondary carcinomas following radiotherapy for carcinoma in other locations, such as the cervix and the head and neck. (38 refs)

- 79-1503 Hyperthermia and Radiation Induced Genetic Aberrations in *Drosophila melanogaster*.** (Eng) Mittler, S. (Dept. Biological Sciences, Northern Illinois Univ., DeKalb, IL, 60115). *Mutat Res* 59(1): 123-128; 1979.

Experiments were carried out in *Drosophila melanogaster* to determine whether hyperthermia could act as a sensitizer for the induction of dominant lethals, recessive lethals and chromosome loss, and nondisjunction by radiation. The number of eggs that hatched following fertilization by males exposed to heat alone (38 C, 1 hr) was unaffected by the heat treatment. However, the number of dominant lethals was increased significantly by subjecting males to heat treatment before or after irradiation (1,000 R), compared with the number induced by irradiation alone. The percentage of dominant lethals was particularly high (83.7%-83.8%) when males were exposed to irradiation and hyperthermia during meiosis I (6- to 8-day brood). Hyperthermia also significantly increased the percentage of radiation-induced recessive sex-linked lethals in three broods (0-2, 2-4, and 4-6 days). Irradiation followed by hyperthermia produced a slight increase in nondisjunction. However, when hyperthermia was applied before irradiation, significant losses of X and Y chromosomes were induced in broods 4-6, 2-4, and 6-8 days. Hyperthermia may cause sensitization to radiation by interfering with repair processes. (14 refs)

- 79-1504 The Induction of Gamma-Endonuclease-susceptible Sites by γ -Rays in CHO Cells and Their Cellular Repair Are Not Affected by the Presence of Thiol Compounds During Irradiation.** (Eng) Van Der Schans, G. P. (Medical-Biological Lab. TNO, Lange Kleiweg 139, 2280 AA Rijswijk Z.H., Netherlands); Centen, H. B.; Lohman, P. H. *Mutat Res* 59(1): 119-122; 1979.

An enzymic assay was used to monitor the disappearance of base damage from Chinese hamster ovary cells following γ irradiation in order to determine whether the ratio of endonuclease-susceptible sites to single-strand breaks could be made higher by the presence of 20 mM cysteamine (CA) during irradiation. DNA was extracted from ^3H -labeled, CA-treated, irradiated cultures at different times after irradiation, incubated with or without a crude cell-free extract of *Micrococcus luteus*, and centrifuged through alkaline sucrose gradients, which were then fractionated. The radioactivity profiles obtained by counting the fractions were subsequently analyzed by computer. From the profiles obtained after treatment with and without the extract, the number of single-strand DNA scissions introduced by γ -specific endonuclease could be determined. CA protected well against γ -

ray-induced single-strand breaks and alkali-labile sites, whereas it did not influence significantly the number of endonuclease-susceptible sites. The rate of repair of endonuclease-susceptible sites was not significantly different for irradiation in the absence or presence of 20 mM CA or 20 mM cysteine. The application of CA during irradiation may aid in the elucidation of different repair processes in human cells. (8 refs)

79-1505 Radiation Exposures of Hanford Workers Dying from Cancer and Other Causes (Letter to Editor). (Eng) Kneale, G. W. (Regional Cancer Registry, Queen Elizabeth Medical Centre, Birmingham B15 2TH, England); Stewart, A. M.; Mancuso, T. F. *Health Phys* 36(1): 87; 1979.

It was not claimed, as previously misunderstood, that cancer was a major hazard of the nuclear industry or that the cancer mortality of Hanford nuclear plant workers was significantly raised, but rather that there is prima facie evidence of a relationship between cancer mortality from certain specific cancers and radiation, even at the low doses received by Hanford workers. This conclusion was confirmed by two additional groups of scientists with access to the same data. They have implicated two of the three cancers named as showing a dose-response relationship (pancreatic cancer and multiple myeloma). (no refs)

79-1506 Cell Survival Following Multiple-Track Alpha Particle Irradiation. (Eng) Lloyd, E. L. (Center Human Radiobiology, Argonne Natl. Lab., Argonne, IL, 60439); Gemmell, M. A.; Henning, C. B.; Gemmell, D. S.; Zabransky, B. J. *Int J Radiat Biol* 35(1): 23-31; 1979.

The survival of mouse embryo fibroblasts (C3H 10T1/2, clone 8) following irradiation with a parallel beam of alpha particles from a Tandem Van de Graaff generator was studied. When plated on plastic Petri dishes, the cells quickly assumed a flattened appearance, and the nuclear area increased from approx 100 to 313 μm^2 . The mean lethal radiation dose for these cells was about 60 rads and an av of 14 alpha particles passed through the nucleus to produce this mean lethal dose. This finding suggests that cells that are similarly flattened against bone surfaces in the body might survive multiple traversals of alpha particles and give rise to malignancies at later times. (16 refs)

79-1507 Low-Intensity Microwave Radiation and the Virulence of *Agrobacterium tumefaciens* Strain B6. (Eng) Moore, H. A. (Dept. Physics, Bradley Univ., Peoria, IL, 61525); Raymond, R.; Fox, M.; Galsky, A. G. *Appl Environ Microbiol* 37(1): 127-130; 1979.

The effects of low-level microwave radiation (10,000 megahertz at 0.58 milliwatt/cm² for 30-120 min) on the virulence

of *Agrobacterium tumefaciens* strain B6 were studied. Exposure of *A. tumefaciens* to microwave radiation resulted in a 30%-60% decrease in their ability to produce tumors on potato and turnip disks. Irradiation resulted in no loss of viability, and there was no loss of virulence or viability when the cells were wrapped in aluminum foil prior to irradiation. The loss in virulence of the unwrapped irradiated cells was not due to an inability to compete for tumor-binding sites or to any major thermal effects. Complete virulence was restored 12 hr after exposure to microwave radiation, although storage at 4 C slowed the restoration to full virulence. It is possible that microwave exposure temporarily alters one or more metabolic processes affecting virulence. (13 refs)

79-1508 Cholangiocarcinoma and Hepatosplenic Atrophy Subsequent to Thorotrast Administration. (Ita) Caresano, A. (Servizio di Radiologia, Ospedale di Circolo, 57 viale Borri, I-21100 Varese, Italy); Conte, L.; Curzio, M.; Provasi, A.; Del Favero, C.; Nanni, R. *Radiol Med (Torino)* 64(11): 1267-1273; 1978.

A woman underwent cerebral angiography with iv Thorotrast (TT). She developed jaundice and died in coma 38 yr later, at the age of 54. Radioactivity was found in the spleen, liver, and lymph nodes. Autopsy revealed a cholangiocarcinoma and atrophy of the liver, spleen, and lymph nodes. The TT dose was estimated to have been 3,000 rads. The high radiation dose and the time lapse justify the hypothesis that the neoplasm was caused by TT. (21 refs)

79-1509 Photodynamic Effects of Dyes on Bacteria. II. Genetic Effects of Broad-Spectrum Visible Light in the Presence of Acridine Dyes and Methylene Blue in Chemostat Cultures of *Escherichia coli*. (Eng) Webb, R. B. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL); Hass, B. S.; Kubitschek, H. E. *Mutat Res* 59(1): 1-13; 1979.

Photodynamic mutagenesis was studied in chemostat cultures of *Escherichia coli* B/r (T1-R *trp*) exposed to one of six acridine dyes of methylene blue (MB). Mutation to phage T5 resistance was induced with a broad-spectrum fluorescent light source. In the presence of light, acridine yellow (AY) was the most effective sensitizing agent for mutagenesis, and quinacrine hydrochloride (Q) the least effective. There was no detectable lethality for any combination of dye concentration and light fluence rate. There was no observable correlation between dye-induced mutation rates in the presence and absence of light; Q gave the largest dark mutation rate. Acridine orange (AO), proflavine (P), and MB mutation rates were proportional to fluence rate and also to dye concentration. Rates of photomutagenesis with AO, MB, or P were independent of growth rate in continuous cultures. The mean-delay period for expression of mutation to phage T5 resistance was also independent of growth rate, the values for various dyes being consistent with an expression delay of 2.5 generations. High concentrations of putrescine or spermidine

did not reduce the rate of AO/light or P/light mutagenesis. The photomutagenic actions of AO and acridine were not additive. The results suggest that photodynamic mutagenesis is due mainly to intercalated dye molecules. (38 refs)

- 79-1510 Increased Susceptibility of Mouse Cells to Fluorescent Light-induced Chromosome Damage After Long-Term Culture and Malignant Transformation.** (Eng) Parshad, R. (Dept. Pathology, Howard Univ. Coll. Medicine, Washington, DC, 20059); Sanford, K. K.; Tarone, R. E.; Jones, G. M.; Baeck, A. E. *Cancer Res* 39(3): 929-933; 1979.

The effects of prolonged time in culture and spontaneous malignant transformation on fluorescent light-induced chromosome damage were studied in mouse NCTC cells. The light-exposed cells showed significant increases in chromatid breaks and chromatid exchanges, and the frequency of meta-centric chromosomes in both shielded and exposed cells increased with time in culture. Increased susceptibility to light-induced chromatid breaks and exchanges occurred in cultures after about 400 days in vitro. Cells from older cultures inoculated into syngeneic hosts grew as sarcomas. In most shielded cultures, the frequency of chromatid breaks and exchanges did not increase with time in culture. Cells of three lines showed a significantly increased susceptibility to both chromatid breaks and exchanges after spontaneous transformation. One cloned line that was unusually resistant to spontaneous transformation was also resistant to light-induced chromosome damage, as was its malignant derivative. The frequency of light-induced chromatid breaks was lower in the nonneoplastic clone than in other mouse cells, although the frequency of light-induced breaks was higher in the malignant derivative than in the nonneoplastic parent clone. Increased susceptibility to light-induced chromatid damage could result from impaired DNA repair or from the loss of defence mechanisms for destroying H_2O_2 or scavenging free radicals. (17 refs)

- 79-1511 Radioactivity in Asbestos.** (Eng) Harley, N. H. (Inst. Environmental Medicine, New York Univ. Medical Center, New York, NY); Cohen, B. S.; Pasternack, B. S.; Fisenne, I. M.; Rohl, A. N. *Environ Int* 1(4): 161-165; 1978.

Total alpha activity and ^{226}Ra activity were measured in five types of asbestos. The ^{226}Ra values varied considerably, with California chrysotile having the lowest value [≤ 0.009 picocuries (pCi)/g] and amosite from the Unarco plant having the highest value (0.35 pCi/g). The total alpha activity varied from 0 [Union Internationale Contre le Cancer (UICC) Cape Blue crocidolite] to 1.4 pCi/g (Unarco amosite). The total alpha activity of the UICC standard amosite and crocidolite (Cape Blue and Transvaal Blue) samples appeared to be lower than that of the same three samples obtained as impure ores. Alpha particles from asbestos fibers immobilized in the lower lung near the pleural surfaces and in the upper lung on bron-

chial surfaces may be implicated in initiating mesothelioma and bronchial carcinoma. (27 refs)

- 79-1512 Kinetics of Intracardially Injected Plutonium-237 Citrate in Channel Catfish (*Ictalurus punctatus*).** (Eng) Trabalka, J. R. (Environmental Sciences Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Eyman, L. D.; Frank, M. L.; Bergman, H. L. *Health Phys* 35(6): 779-784; 1978.

Plutonium-237 (^{237}Pu) distribution and translocation were studied in channel catfish (*Ictalurus punctatus*) following intracardial injection of ^{237}Pu citrate (0.075 ml of 1 μCi $^{237}Pu/cm^3$ saline soln). Fish were sacrificed at 1, 2, 3, 10, and 17 days after injection. Plasma contained 90% or more of the blood-associated ^{237}Pu . Within the plasma from a control fish spiked with ^{237}Pu and incubated at 3 C for 24 hr, 72% of the Pu was contained in one fraction, the iron-binding globulin transferrin. The fractional body burdens in bone, liver, and kidney 17 days after injection were 31%, 24%, and 9% of the injected dose, respectively. High kidney burdens relative to mammals were expected, since the kidney functions as the major site of hemopoiesis in teleosts. Five of the 10 ovaries sampled contained ^{237}Pu concentrations comparable to liver values, but the remaining 5 ovaries carried concentrations similar to those in bone and gill. Muscle and skin contained 31% of the body burden on day 1, but this value fell to 16.6% on day 17. Excretion over the 17-day period was $\leq 10\%$. The absence of significant excretion indicates that a short half-life component of elimination following gut clearance in earlier gavage studies is due to Pu labeling of the gut. The results suggest that assimilated Pu should be insignificant in aquatic food chain transfers. (24 refs)

- 79-1513 Carcinogenicity of Inhaled Air-oxidized $^{239}PuO_2$ in Rats.** (Eng) Sanders, C. L. (Dept. Biology, Pacific Northwest Lab., Richland, WA, 99352); Mahaffey, J. A. *Int J Radiat Biol* 35(1): 95-98; 1979.

The metabolism and carcinogenicity of inhaled air-oxidized (AO) $^{239}PuO_2$ were studied in random-bred female specific-pathogen-free Wistar rats, and the results were compared with those obtained previously using high-fired (HF) $^{239}PuO_2$. The animals were exposed for 30 min at 70 days of age. During the first few weeks after exposure, HF and AO particles were scattered throughout the lung parenchyma. All the alpha tracks for HF and 90% of those for AO $^{239}PuO_2$ that were deposited in the lung were in the form of stars. About 40% of the initial alveolar deposition (IAD) of the HF particles and about 28% of that of the AO particles remained in the lung 30 days after exposure. More AO than HF $^{239}PuO_2$ was translocated from the lung into the liver and skeleton. Four HF-exposed rats exhibited two different types of primary lung tumor, whereas none of the AO-exposed rats exhibited more than one lung tumor. The primary lung tumors produced, in decreasing order of frequency, were adenocarcinoma, squamous cell carcinoma, hemangiosarcoma, meso-

thelioma, and fibrosarcoma. The incidence of lung tumors in AO- and HF-exposed rats was significantly increased over control values. However, lung tumor incidence with an AO IAD of 9.9 nanocuries (nCi) was significantly greater than that with an HF IAD of 5.5 nCi (28% vs 10%), but not significantly less than that with an HF IAD of 45 nCi (37.4%). This suggests that AO $^{239}\text{PuO}_2$ was more efficient in inducing lung tumors than HF $^{239}\text{PuO}_2$, possibly due to a more uniform exposure of lung cells with the former. (6 refs)

79-1514 Influence of the Mass of Administered Plutonium on Its Cross-placental Transfer in Mice.

(Eng) Weiss, J. F. (Comparative Animal Res. Lab., 1299 Bethel Valley Road, Oak Ridge, TN, 37830); Walburg, H. E. *Health Phys* 35(6): 773-777; 1978.

The mass effect for placental transport of plutonium (Pu) was studied in BALB/c mice. Pregnant mice were injected in the tail vein with one of three doses of $^{239}\text{Pu(IV)}$ citrate 16 days after mating (0.098, 2.38, or 26.91 $\mu\text{Ci/kg}$ in one experiment and 0.10, 2.41, and 26.56 $\mu\text{Ci/kg}$ in another). The mice were killed and tissues prepared for analysis 48 hr after injection. There was an inverse relationship between mass of Pu administered and amount transferred to the fetuses, placentas, and maternal tissues. No significant differences in percentage of dose incorporated were observed in similar tissues between the two lower dose levels (av values of both experiments combined): fetus, 4.76% and 4.37%; placenta, 15.75% and 14.60%; maternal femur, 1.47% and 1.51%; and remainder of maternal carcass, 59.82% and 63.51%. The highest dose level showed a significantly reduced percentage of dose incorporated into fetus (1.29%), placenta (7.09%), and maternal femur (0.76%). There was a significantly higher percentage of incorporation in the remainder of the carcass at the highest dose (72.67%). These data indicate that estimates of cross-placental transfer of Pu and fetal uptake at low dose levels derived from observations at high doses are likely to be in error. (13 refs)

79-1515 Calculated MPC-a Values for $^{239}\text{PuO}_2$ By Comparing the Added Risk of Cancer with the Accepted Occupational Risks.

(Eng) De Bont, A. H. (Dept. Health Physics, Univ. Nijmegen Toernooiveld Nijmegen, Holland 6525 ED); Beentjes, L. B. *Health Phys* 36(1): 53-58; 1979.

Values of the max permissible concentration in air (MPC-a) of $^{239}\text{PuO}_2$ were calculated by comparing the added risk of cancer with the accepted occupational risks. Specifically, the risks of cancer induction in bone, lungs, liver, and tracheo-bronchial lymph nodes was considered. Two deposition and distribution models were used: the New Lung model (NLM) and a modification of this model (NLMP) that corrects for the effect of particle size on the rate of removal of radioactive material from the lungs. It was assumed that MPC-a should be chosen such that the risk incurred by exposure for 40 hr/wk over 50 yr would still be acceptable; $1 \times 10^{-4}/\text{yr}$ was

taken as an acceptable risk rate. When the NLM was used, the lung was the organ subject to the highest cancer induction risk. When the NLMP was used, the lung was again the critical organ, especially with particle sizes $\geq 1 \mu\text{m}$ activity median aerodynamic diameter (AMAD); the liver was the critical organ with particle sizes of 0.1-0.01 μm AMAD. The possibility that at small doses cancer induction risk may not be linearly related to dose was not considered. Limitation of the cancer induction risk rate to $1 \times 10^{-4}/\text{yr}$ implies a reduction of the max permissible dose equivalent for the total body by a factor of 6. (12 refs)

79-1516 ^{90}Sr in Placentas, Embryos and Foetuses of Mice, Evaluated by Whole-Body Autoradiography.

(Eng) Olsen, I. (Dept. Microbiology, Dental Faculty, Univ. Oslo, Blindern, Oslo 3, Norway); Jonsen, J. *Acta Pharmacol Toxicol (Kbh)* 44(1): 22-27; 1979.

Whole-body autoradiography was used to study the fetal uptake and retention of ^{90}Sr (single dose of 50 μCi , given ip within days 5-18 of gestation) and the embryonic transfer of this isotope as a function of gestational age. The pregnant dams were killed 15 min to 72 hr after injection. ^{90}Sr was found in the visceral yolk sac and chorioallantoic placenta 15 min after injection on gestation day 14. These concentrations declined by 24 hr after injection and were not detectable at 72 hr. ^{90}Sr was first seen in the 14-day-old fetus 4 hr after injection; the concentrations in the soft tissues peaked at 12 hr and were not detectable at 72 hr, whereas those in the hard tissues continued to increase. ^{90}Sr passed the placental barriers throughout gestation, being found in all fetuses and the visceral yolk sac on days 5-18. The isotope did not appear in the chorioallantoic yolk sac until day 11. ^{90}Sr gradually accumulated in preskeletal and skeletal tissues, the distribution becoming more differentiated and more like that of the mother with increasing gestational age. Intake of ^{90}Sr during early gestation may be more injurious to the offspring than intake during late gestation. (21 refs)

79-1517 Solvent Extraction Method for Determination of Thorium in Soft Tissues.

(Eng) Singh, N. P. (Inst. Environmental Medicine, New York Univ. Medical Center, 550 First Ave., New York, NY, 10016); Ibrahim, S. A.; Cohen, N.; Wrenn, M. E. *Anal Chem* 51(2): 207-210; 1979.

A method for the determination of thorium isotopes in soft tissues consists of preliminary nitric acid digestion of tissues after adding ^{229}Th tracer followed by digestion with a mixture of nitric and sulfuric acid plus occasional addition of a few drops of H_2O_2 ; thorium is then coprecipitated with iron carrier by ammonium hydroxide. The compound is extracted into trilaurylamine + xylene and determined by α spectrometry with a surface-barrier silicon detector. Final total recovery ranged from 24%-93% with a mean of 65% in 28 samples. (10 refs)

- 79-1518 Osteosarcoma Associated with Thorotrast Administration: Report of Two Cases and Literature Review.** (Eng) Sindelar, W. F. (Surgery Branch, NCI, NIH, Bethesda, MD, 20014); Costa, J.; Ketcham, A. S. *Cancer* 42(6): 2604-2609; 1978.

The occurrence of osteosarcoma in two patients who had undergone angiography with Thorotrast in childhood is reported, and similar cases in the literature are reviewed. In both patients, there was radiographic and pathologic evidence of thorium dioxide deposition in bone and throughout the reticuloendothelial system. Thorotrast deposits were demonstrated in the immediate vicinity of the primary tumors by both histologic and autoradiographic studies. (21 refs)

- 79-1519 Effect of Receiver Orientation on Erythema Dose.** (Eng) Burt, J. E. (Dept. Geography, Univ. California, Los Angeles, CA, 90024); Luther, F. M. *Photochem Photobiol* 29(1): 85-91; 1979.

The significance of receiver orientation (inclination angle and azimuth angle) to the solar flux dose received in the wavelength region responsible for erythema (sunburn) and skin cancer was determined. A semiempirical model was used to calculate erythema dose for nonhorizontal plane areas under cloudless conditions as a function of latitude, season, and ozone amount. According to the model, in middle and high latitudes, surfaces with inclination angles (α) up to 45 degrees receive at least 80% of the daily erythema dose received by a horizontal surface. Much larger reductions in daily erythema dose occur for $\alpha > 45$ degrees, which can result in a significant reduction in the latitudinal gradient of erythema dose. The amplification factor for erythema dose ($\Delta\text{dose}/\Delta O_3$) varies significantly with latitude, but it is only weakly dependent upon receiver orientation. Additional calculations indicate that the amplification factor may be significantly larger for skin cancer than for erythema. (31 refs)

- 79-1520 Alpha Irradiation of the Skin and the Possibility of Late Effects.** (Eng) Sevcova, M. (Dept. Dermatology, Health Inst. Uranium Industry, 261 00 Pribram, Czechoslovakia); Sevc, J.; Thomas, J. *Health Phys* 35(6): 803-806; 1978.

Exposure of uranium miners to alpha radiation is important because of contamination of the skin surface by radon (^{222}Rn) daughters. Based on data on epidermal thickness, which is less than 50 μm or 5 mg/cm^2 on the face and trunk in 50% of humans, an estimate was made of the dose equivalent delivered to the basal layer of the epidermis. In Czechoslovak uranium miners working 1,700 hr/yr, the mean dose equivalent in the basal layer of the epidermis will be 60 rem (roentgen-equivalent-man)/yr. In persons having a thin epidermis, the dose equivalent will be two times higher. Before the initiation of current standards, the concentration of radon daughters in uranium mines exceeded the current permissible value by approx 10 times, allowing the cumulative dose equivalent

to reach several thousands of rem following an exposure of many years duration. In a group of several thousand uranium miners, the incidence of skin cancer (mainly basal cell carcinoma) during 1968-1975 was significantly higher than expected, particularly among miners with > 10 yr exposure. These results indicate the possibility of a carcinogenic effect of external alpha irradiation of the skin. (12 refs)

- 79-1521 Giant Cell Tumor after Exposure to Cobalt-containing Dust: Cobaltous Phthalocyanine (Merox Catalyst).** (Ger) Schulz, G. (Arbeitsmedizin Ltd., Dtsch. B.P. A.G., Mexikoring 23, 2000 Hamburg 60, W. Germany). *Staub-Reinhalt Luft* 38(12): 480-481; 1978.

A 49-yr-old oil refinery worker developed a fast-growing giant cell tumor in his cheek 5 mo after his oral and buccal membranes were accidentally exposed to dust containing cobaltous phthalocyanine, a mercox catalyst. The recurring tumor was a foreign body granuloma that contained Langhans giant cells and cobalt salts. (7 refs)

- 79-1522 Differentiated Thyroid Cancer Following Radioiodine ^{131}I Therapy of Hyperthyroidism--A Case Report.** (Eng) Nemec, J. (Res. Inst. Endocrinology, 115 94 Prague, Czechoslovakia); Soumar, J.; Zeman, V.; Nahodil, V.; Zamrazil, V.; Smejkal, V. *Oncology* 35(6): 277-280; 1978.

The case of a 65-yr-old man who developed differentiated (papillary) thyroid cancer 17 yr after ^{131}I treatment for toxic multinodular goiter is presented, and 21 similar literature cases are summarized. The paucity of ^{131}I -associated thyroid cancers in comparison with those associated with external radiation may be due to differences in absorbed dose. (26 refs)

- 79-1523 Development of Carcinoma of the Breast at the Site of an Implanted Pacemaker in Two Patients.** (Eng) Biran, S. (Dept. Oncology, Hadassah Univ. Hosp., Jerusalem, Israel); Keren, A.; Farkas, T.; Stern, S. *J Surg Oncol* 11(1): 7-11; 1979.

Two women who had permanent pacemakers (PM's) implanted in their chests subsequently developed breast carcinoma. Patient 1 (64 yr old) had undergone a left radical mastectomy + radiation therapy in 1953 because of carcinoma simplex of the breast. A PM was implanted into the right subclavicular area in 1975 because of alternating second- or third-degree block with junctional rhythm. In 1977, a firm mass was noted in the patient's right breast, slightly below the PM box. The biopsy result was positive for intraductal-type carcinoma. Patient 2 (65 yr old) had a PM implanted for complete atrioventricular block in the subclavicular area of the right chest, bordering the right breast. Several months later, a discharge from the nipple of her right breast was noted. Subsequent physical exam revealed a mass slightly above the nipple and two enlarged lymph glands in the right

axilla. Biopsy 18 mo after PM implantation showed adenocarcinoma and Paget's disease. Because a connection between mammary carcinoma and the PM is suspected, the site of the sc pocket for implanting the PM in female patients was changed to a position higher in the chest, to avoid contact between the PM and the mammary tissue. (14 refs)

- 79-1524 Induction of Pulmonary Carcinoma in Rats by Chronic Inhalation of Dust from Pulverized Asbestos Pipe Covering.** (Eng) Leong, B. K. (International Res. and Development Corporation, 500 N. Main St., Mattawan, MI, 49071); Kociba, R. J.; Pernell, H. C.; Lisowe, R. W.; Rampey, L. W. *J Toxicol Environ Health* 4(4): 645-659; 1978.

Fifty male Sprague-Dawley rats and 15 male golden hamsters were exposed to dust generated by pulverization of prefabricated asbestos pipe covering (PAPC) and observed for subsequent development of pulmonary disease. Animals were exposed to dusts containing 0.5- to 10.5- μ m particles (mean diameter, 4.1 μ m) and very few fibers at a concentration of 85 mg/m³ for 6 hr/day, 5 days/wk, over 7 mo (150 total exposures). Five experimental and five control rats were sacrificed at the end of exposure or at 1, 6, and 18 mo postexposure (PE). Otherwise animals were allowed to die naturally. The mean body wts of the rats were significantly lower than those of controls until 14 mo PE, but there was no difference in mortality between the groups. Up to 6 mo PE, pulmonary deposits of dust were visible grossly as isolated subpleural pale foci, and isolated aggregates of dust-laden macrophages were visible microscopically within alveoli. However, there were no marked accumulations of intraalveolar proteinaceous material, WBC, inflammatory debris, or fibrogenic responses. At 14-29 mo PE, there were instances of alveolar hyperplasia, alveolar adenomatous proliferation, nonprogressive fibrosis, and squamous metaplasia of alveoli. Moreover, 6/34 rats had pulmonary carcinomas compared with 0/35 controls. Eight hamsters died early during the exposure period, two with pulmonary lesions. In the seven surviving animals, all of which died within 17 mo, there were isolated aggregates of particle-laden macrophages, and three hamsters displayed minimal focal alveolar epithelial hyperplasia. None of the hamsters developed tumors. The dust used is the type to which pipe insulation workers may be exposed. (24 refs)

- 79-1525 Thorotrastosis--Viewed in Retrospect.** (Ger) Autenrieth, J. (Strahlenklinik, Freie Universitat Berlin im Klinikum Charlottenburg, Spandauer Damm 130, 1000 Berlin 19, W. Germany); Lange, S. *Roentgenblaetter* 32(2): 71-74; 1979.

Two tumors attributable to the diagnostic use of Thorotrast (TT) are reported and the literature on thorotrastosis is reviewed. A 61-yr-old woman developed hepatocellular carcinoma plus fibrosis and atrophy of the spleen 29 yr after TT angiography of the cerebral vessels. Another woman developed a foreign-body granuloma of the thigh several years after TT angiography of the pelvic and femoral region. Typi-

cal TT deposits were found in the liver, spleen, and perigastric lymph nodes. (14 refs)

- 79-1526 Thorotrast Induced Hepatic Cholangiocarcinoma and Angiosarcoma.** (Eng) Winberg, C. D. (Dept. Pathology, Stanford Univ. Sch. Medicine, Stanford, CA); Ranchod, M. *Hum Pathol* 10(1): 108-112; 1979.

A 49-yr-old woman developed hepatic cholangiocarcinoma and angiosarcoma 22 yr after the administration of Thorotrast (TT: colloidal thorium dioxide) for cerebral arteriography. Abdominal roentgenograms revealed regions of very high density in the liver and spleen that were interpreted as residual TT. TT granules were found in a liver biopsy specimen. This is the first report of the simultaneous occurrence of two different hepatic tumors in association with TT exposure. (21 refs)

- 79-1527 Thorotrast Associated Hepatic Angiosarcoma with 36 Years Latency.** (Eng) Underwood, J. C. (Dept. Pathology, Univ. Sheffield Medical Sch., Beech Hill Road, Sheffield S10 2RX, England); Huck, P. *Cancer* 42(6): 2610-2612; 1978.

Radiological and autoradiographic findings in a case of hepatic angiosarcoma that developed 36 yr after thorotrast administration are reported. The patient had received a total of 23 ml of the agent at the age of 9. A needle liver biopsy, examined 3 mo before death, showed a spindle cell vascular neoplasm insinuating between liver cells. Autoradiography demonstrated that the neoplasm was associated with granular thorium deposits. (7 refs)

- 79-1528 Haemangioendothelioma (Kupffer Cell Angiosarcoma), Myelofibrosis, Splenic Atrophy, and Myeloma Paraproteinaemia After Parenteral Thorotrast Administration.** (Eng) Jennings, R. C. (Altrincham General Hosp., Cheshire, England); Priestley, S. E. *J Clin Pathol* 31(12): 1125-1132; 1978.

The case report of a 74-yr-old woman with Thorotrast (TT: thorium dioxide suspension)-induced multifocal hepatic hemangioendothelioma (Kupffer cell angiosarcoma), splenic atrophy, myelofibrosis, and myeloma-type paraproteinemia is presented. In 1952, 25 yr prior to the diagnosis, she had been given 45 ml TT parenterally for a carotid angiogram. Histologically, the liver showed prominent TT pigment deposition, mainly in the portal tracts and to a lesser extent scattered throughout the parenchyma with a variable amount of intervening normal hepatic tissue. Multiple blood-containing cysts were present that, at their inception, were lined by a single layer of phagocytic tumor cells; as they enlarged, they revealed both solid and papillary intracystic tumor cell groups. The spleen showed pronounced pigment deposition. Between the large focal groups of pigment granules, there was a fibrosing cellular parenchyma with some necrosis but virtu-

ally no residual normal splenic tissue. Bony myelomatous deposits together with paraproteinemia were also found. The parietal bone showed two hemorrhagic cystic lesions with plasma cell groups within the cystic spaces. The bone marrow from the sternum and iliac crest showed some pigment deposition with alternating areas of hyperplasia and myelofibrosis and, in addition, focal aggregates of plasma cells. There was a diffuse chronic thyroiditis with reduction in colloid acinar production but with no pigment deposition. This is the first recorded association of TT angiography and myeloma-type paraproteinemia. The relationship between TT-induced hemangioendothelioma and other vascular sarcomas of the liver is reviewed briefly. (22 refs)

- 79-1529 Variation of Properties of Chrysotile Asbestos Subjected to Milling.** (Eng) Langer, A. M. (Environmental Sciences Lab., Dept. Community Medicine, Mount Sinai Sch. Medicine, City Univ. New York, Fifth Ave. and 100th St., New York, NY, 10029); Wolff, M. S.; Rohl, A. N.; Selikoff, I. J. *J Toxicol Environ Health* 4(1): 173-188; 1978.

Chrysotile asbestos samples were milled for 60-3,600 sec and then examined for alteration of surface or structural properties by electron microscopy, x-ray diffraction analysis, infrared spectroscopy, and electron spin resonance. The hemolytic activity and adsorption of diphenylpicrylhydrazyl (DPPH) to chrysotile were also investigated. The milling decreased fiber crystallinity, altered silicon-oxygen and magnesium-oxygen interlayer bonding, induced coordination changes in the brucite layer, diminished the ability of the fiber to reduce and physisorb DPPH, and decreased hemolytic potency and antagonist sorption capabilities. The degree of alteration was related to the duration of milling. The hypothesis that particle shape is the major etiologic mechanism in fibrotic or carcinogenic responses appears, in terms of these results, to be oversimplified, except insofar as morphology reflects more fundamental structural and surface physicochemical properties. Comparison of biological potentials of fibers of different lengths should take into account alterations of fiber characteristics by the preparation of various size fractions. (46 refs)

- 79-1530 Incidence of Gastric Cancer after Vagotomy and Pyloroplasty in the Rat.** (Eng) Junghanns, K. (Surgical Dept., Univ. Heidelberg, Heidelberg, W. Germany, Switzerland). *Chir Gastroenterol* 12(1): 27-29; 1978.

To study the effects of vagotomy and pyloroplasty on tumor induction, 1-methyl-3-nitro-1-nitrosoguanidine (MNG: 4 mg/day in the drinking water) was given to Wistar rats, some of which had undergone truncular vagotomy and pyloroplasty. Tumors developed in 93.5% of the operated rats after a mean dose of 1.8 g MNG and a median induction time of 430 days. Tumors developed in 75.5% of the control rats after a mean dose of 2.2 g MNG and a median induction time of 565 days. Most of the tumors were adenocarcinomas, and

they were most common in the glandular stomach and pylorus, especially in the operated rats; tumors of the duodenum and jejunum appeared more frequently in the controls. Both groups showed a large number of hepatic cysts. The operated and control groups did not differ statistically in terms of median induction time, mean dose of MNG, or tumor distribution. The data indicate that unlike gastric resection, vagotomy and pyloroplasty do not make the stomach more susceptible to the effects of exogenous carcinogens. (8 refs)

- 79-1531 Iodine-131 and Malignancy (Letter to Editor).** (Eng) Warner, T. F. (Dept. Pathology, Indiana Univ. Sch. Medicine, Indianapolis, IN, 46202). *Lancet* 1(8106): 38; 1979.

A multifocal adenocarcinoma of the proximal jejunum occurred in an 89-yr-old woman 18 yr after the ingestion of two 15-mCi doses of iodine-131 for toxic multinodular goiter. Widespread mucosal hyperplasia, dysplasia, and carcinoma in situ were present. Apart from three infiltrating tumors, three distinct histological types of adenocarcinoma were seen in other areas. These changes are suggested to be due to the ¹³¹I exposure. (5 refs)

- 79-1532 Induction of Bladder Carcinomas in Dogs.** (Eng) Gericke, D. (Hoechst AG, D-6230 Frankfurt, W. Germany); Harzmann, R.; Bichler, K. H.; Altenahr, E. *Naturwissenschaften* 65(12): 665-666; 1978.

The induction of experimental bladder carcinoma, using polymerizing plastic pellets with or without carcinogen treatment, was studied in four groups of dogs. The pellets were used to induce local irritation of the urothelium. In the first group, 1.5 ml of the fluid phase of the plastic methyl methacrylate were injected into the saline-filled urinary bladder. Polymerization occurred within 90-150 sec. In the second group, the plastic treatment was combined with o-aminodiphenyl treatment (30 mg/kg, twice weekly, sc). In the third group, plastic treatment was combined with 2-formylamino-4-(5-nitro-2-furyl)thiazole (FANFT) treatment (25 mg/kg, twice weekly, sc) and in the fourth group, it was combined with both carcinogens (20 mg/kg each, twice weekly). Carcinoma was diagnosed histologically between the 13th and 18th mo in 7/8 dogs in Groups 3 and 4. No animals in Groups 1 or 2 or in the control group showed invasive carcinoma or carcinoma in situ of the urothelium. (12 refs)

- 79-1533 Effects of Intraperitoneal Administration of Asbestos and Asbestos-Quartz Mixtures on Rats.** (Ger) Weller, W. (Silikose-Forschungsinstitut, Bergbau-Berufsgenossenschaft, Hunscheidtstrasse 12, D-4630, Bochum 1, W. Germany). *Int Arch Occup Environ Health* 42(3/4): 169-183; 1979.

The pathogenicity of chrysotile B (CT), crocidolite (CL), and quartz (QZ), alone and in combination, was studied in 197

1-yr-old female SPF Sprague-Dawley rats. Dusts of the minerals were suspended in physiological saline. When the substances were administered singly, the rats received 5, 10, or 15 mg in 1 ml saline ip. When they were administered in combination, the rats received 5, 10, or 15 mg QZ plus 15, 10, or 5 mg of either asbestos compound (each combination totaled 20 mg). Rats from each treatment group were sacrificed at 3 and 6 mo. Administration of QZ alone caused a dose-dependent increase in spleen and omentum wt; the other dusts and mixtures did not have this effect. The wts of the pulmonary lymph nodes and/or cranial mesenteric lymph nodes were clearly correlated to dust injections. The values were significantly higher with CL than with CT. With QZ + CL, the effects were additive; QZ + CT had an inhibitory effect. CL caused widespread adhesions in the omentum, spleen, liver, and diaphragm. CL alone or with QZ produced ascites and ovarian cysts. One or two mice in each experimental group (total, 12 mice) had sc fibroadenomas; these tumors were not seen in the controls. No asbestos fibers could be found in these tumors, and their significance is not clear. Fibrous (Grade III) granulomas were numerous in all CL groups; many asbestos fibers were seen at the highest dose. Ferruginous bodies were first noted at 6 mo in the group given the highest dose of CL. No signs of progression toward malignancy were seen in any of the lesions. (37 refs)

79-1534 Analysis of the Cores of Asbestos Bodies from the General Population: Correlation of Amphibole Subtypes and Sex (Meeting Abstract). (Eng) Churg, A. (Dept. Pathology, Univ. California, San Francisco, CA, 94143); Warnock, M. L. *Lab Invest* 40(2): 246-247; 1979. (no refs)

79-1535 Analysis of Asbestos Fibers in Various Alcoholic Beverages: Role of Contamination by Filtration Materials. (Fre) le Bouffant, L. (Centre d'études et recherches des Charbonnages de France, BP 2, 60550 Verneuil-en-Halatte, France). *Ann Nutr Aliment* 32(5): 1011-1019; 1978.

Samples of alcoholic beverages that had not been filtered or that had been filtered through asbestos were examined for the presence of asbestos fibers. The samples were filtered on a micropore membrane, and the membrane was examined un-

der an electron microscope. The fibers were identified by their morphology and x-ray diffraction pattern and, in some cases, by elemental microanalysis. All asbestos-filtered samples showed chrysotile fibers that generally occurred separately, although sometimes they were found in clumps. The unfiltered samples showed only small amounts of fibers, similar to the amounts found previously in water samples. (no refs)

79-1536 Use of Transmission Electron Microscopy for the Analysis of Chrysotile Asbestos in Wine. (Fre) Dufour, G. (Laboratoire d'étude des Particules Inhalées, Direction des Affaires Sanitaires et Sociales de Paris, 37 bd Saint-Marcel, 75013 Paris, France); Sebastien, P.; Gaudichet, A.; Bignon, J.; Bonnaud, G. *Ann Nutr Aliment* 32(5): 997-1009; 1978.

A method for analyzing chrysotile asbestos fibers in wines involves isolation of particles by microfiltration through a nucleopore membrane and entrapment of retained particles in a carbon layer. This layer is observed under a transmission electron microscope fitted with an x-ray-scattering spectrometer. Chrysotile fibers are identified on the basis of morphology, elemental composition, and crystal structure. (29 refs)

VIRAL CARCINOGENESIS

- 79-1537** **Defectiveness of Avian Erythroblastosis Virus: Synthesis of a 75K gag-related Protein.** (Eng) Hayman, M. J. (Dept. Tumour Virology, Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Royer-Pokora, B.; Graf, T. *Virology* 92(1): 31-45; 1979.

Nonproducer clones of Spafas chicken fibroblasts or erythroblasts transformed by strains R and ES4 of avian erythroblastosis virus (AEV) were isolated and characterized. They did not release virus particles detectable by ³H-uridine incorporation or reverse transcriptase assays. Transforming virus could be rescued from these clones by superinfection with avian leukosis viruses of subgroups A, B, C, and D. Analysis of ³⁵S-methionine-labeled cell extracts of the non-producer clones by immune precipitation showed that none of the three viral structural protein precursor polyproteins, Pr76gag, gPr95env, and Pr180gag-pol, were synthesized. Instead, a 75,000-dalton protein (AEV 75K) was isolated. By using specific antisera, this protein was shown to be antigenically related to the gag gene, but not to the pol or env genes. Pulse-chase experiments showed that the AEV 75K protein was turned over, but none of the major structural proteins (p27, p19, or p15) could be detected after the chase. Nonproducer cells expressed inhibitory activity only for p19 in competition radioimmunoassays; no inhibitory activity related to p27 or p15 could be demonstrated. Tryptic peptide analysis of the AEV 75K protein confirmed the immunological data in that the fingerprint of this protein was distinct from those of Pr76gag, gPr95env, and the β -subunit of reverse transcriptase. AEV 75K may play a role in transformation. (44 refs)

- 79-1538** **Ultrastructural Study of Avian Myelocytomatosis Virus (MC 29).** (Fre) Gogusev, J. (Laboratoire de Medecine experimentale, College de France, 11, place Marcelin-Berthelot, 75231 Paris Cedex 05, France); Heine, U. *C R Acad Sci [D] (Paris)* (287): 1075-1078; 1978.

The ultrastructure of the avian myelomatosis virus (MC 29) genome was studied in chick fibroblast cultures by electron microscopy, using a sucrose gradient to separate the high-mol-wt RNA's. Six dimers were found in the 100 molecules counted. The overall length of the molecules varied, which is indicative of degradation of the distal parts of the polynucleotide chain. The dimeric structures contained dimeric linkage structures but no hairpin loops. The length of the dimeric linkage structures averaged 3.8 μ m. After denaturation, the mean length of the 28S fraction was 1,248 μ m, which corresponds to a mol wt of 1.50×10^6 daltons. The 34S fraction had a length of 2,125 μ m and a mol wt of 2.55×10^6 daltons. (12 refs)

- 79-1541** **Immunofluorescence on Avian Sarcoma Virus-transformed Cells: Localization of the src Gene Product.** (Eng) Rohrschneider, L. R. (Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA, 98104). *Cell* 16(1): 11-24; 1979.

The localization of the avian sarcoma virus src gene product (p60src) was examined by indirect immunofluorescence (IF) in chicken embryo fibroblasts (CEF) and normal rat kidney (NRK) cells transformed by the Schmidt-Ruppin strain of Rous sarcoma virus, subgroup D (SR-RSV-D). Antitumor serum precipitated p60src from SR-RSV-D-transformed CEF but not from CEF infected with a transformation-defective (td) mutant of SR-RSV-D. All viral structural proteins and precursors contained in these immunoprecipitates could be eliminated by competition with unlabeled virus. Similar results were obtained with NRK cells transformed by SR-RSV-D (SR-RK). With acetone-fixed cells, p60src-specific IF revealed a principal fluorescence pattern in both cell systems that was diffuse and situated in the cytoplasm. IF on formaldehyde-fixed cells also indicated the cytoplasmic location of p60src and revealed a specific subcytoplasmic concentration of the fluorescence. An additional fluorescence pattern was seen between cells in contact in both SR-RK and SR-RSV-D-transformed CEF. IF on viable cells suggested that p60src was not on the surface of these transformed cells. The fluorescence patterns were specific for avian sarcoma virus-transformed cells and were not found in uninfected cells, cells infected with a td mutant of SR-RSV-D, or cells transformed by an antigenically unrelated murine sarcoma virus. (46 refs)

- 79-1542** **Dissociation of Transformation Parameters Using Temperature-conditional Mutants of Rous Sarcoma Virus.** (Eng) Weber, M. J. (Dept. Microbiology, Univ. Illinois, Urbana, IL, 61801); Friis, R. R. *Cell* 16(1): 25-32; 1979.

Two alternative explanations were considered for the partial transformation properties of tsG1251, a mutant of Rous sarcoma virus that induces a partially transformed phenotype at 42 C: (1) the *src* gene product could have more than one intracellular target, and (2) tsG1251 could be a leaky mutant. Secondary cultures of chf chicken embryo body walls were infected with a variety of temperature-conditional transformation mutants at temperatures between the restrictive and permissive temperatures (36, 38, 40, or 42 C), and the following parameters of transformation were measured 2 days after the final plating: growth in soft agar, growth in the absence of serum, density-dependent growth inhibition, LETS (large, external, transformation-sensitive) protein on the surface, hexose transport rate, plasminogen activator activity, and adhesion to the culture dish. The properties of tsG1251 could not be mimicked by making any of the other mutants leak. Although all the transformation parameters varied coordinately with temperature in most of the mutant-infected cells, cells infected with tsG1251, while thermosensitive for cellular parameters of transformation, were cold-sensitive for growth. These results indicate that tsG1251 is not simply a leaky mutant and raises the possibility that *src* has more than one primary intracellular target. An alternative explanation for the dissociation of growth properties from cellular manifestations of transformation is that the tsG1251 *src* protein is altered either in its regulation or structure in such a way as to become growth inhibitory at low temperatures in cells infected with this mutant. (33 refs)

79-1543 Effects of Inhibitors of Lipid Synthesis on Transformation in Chick Embryo Fibroblasts Infected with Rous Sarcoma Virus. (Eng) Harley, J. B. (Dept. Internal Medicine, Yale Univ., New Haven, CT, 06510); Goldfine, H. *Exp Cell Res* 118(1): 47-54; 1979.

The effects of two inhibitors of lipid synthesis [25-hydroxycholesterol (HC) and cerulenin] on early events in the transformation of chicken embryo cells by a temperature-sensitive mutant of Rous sarcoma virus (RSV *tsLA24*) were studied. HC caused a dose-dependent inhibition of growth in uninfected cells and inhibited sterol synthesis in RSV *tsLA24*-infected cells. When infected cells were treated with HC starting 12 hr before shiftdown from the nonpermissive temperature (41 C) to the permissive temperature (35 C) or with cerulenin starting 2 hr before shiftdown, they were initially able to increase their uptake of 2-deoxyglucose. They were unable to maintain this enhanced rate, however, and the rate of 2-deoxyglucose uptake decreased to the level of the controls at the nonpermissive temperature. As indicated by ³H-thymidine uptake, the ability of RSV *tsLA24*-infected cells to enter the S phase when shifted to 35 C in serum-free medium was not inhibited by HC. It appears that in this system the early events of transformation can occur in a completely defined medium and that these early events do not require normal rates of sterol synthesis. (22 refs)

79-1544 The NH₂-Terminal Sequence of the Avian Oncovirus *gag* Precursor Polypeptide (Pr76gag).

(Eng) Palmiter, R. D. (Dept. Biochemistry, Univ. Washington, Seattle, WA, 98195); Gagnon, J.; Vogt, V. M.; Ripley, S.; Eisenman, R. N. *Virology* 91(2): 423-433; 1978.

To study the NH₂-terminal sequences of the avian oncovirus *gag* precursor polypeptide Pr76gag, 35S RNA from the Prague strain of Rous sarcoma virus (PR-RSV) was used to program the in vitro synthesis of Pr76gag under conditions that prevented acetylation of the NH₂-terminus. Using automated Edman degradation, the NH₂-terminal sequence of Pr76gag was identified as Ac-Met-Glu-Ala-Val-Ile-Lys-Val-Ile-X-X-Ala-X-Lys. This sequence represented the primary translation product and was not derived by processing of a precursor. Determination of the amino acid composition of the 19a and 19d peptides of the p19 virion protein indicated that 19a was probably the NH₂-terminal peptide of both Pr76gag and p19. The amino acid composition of the 19d peptide was not consistent with its lying at the NH₂ terminus of Pr76gag. Annealing the tRNA-Trp primer for reverse transcriptase to 35S viral RNA did not interfere with the synthesis of Pr76gag. Comparison of the amino acid sequence of Pr76gag with the previously reported nucleotide sequence of the 5' end of 35S RNA from PR-RSV showed that synthesis of Pr76gag is not initiated within the first 119 nucleotides of the viral genome. (36 refs)

79-1545 The Kinetics of Synthesis in Infectious Unintegrated Virus DNA in Rous Sarcoma Virus Infected Chicken Cells. (Eng) Stedman, N. (Dept. Cellular and Molecular Biology, Inst. Cancerology and Immunogenetics, Villejuif, France); Mariage, R.; Goubin, G.; Hillova, J.; Hill, M. *J Gen Virol* 42(1): 207-213; 1979.

The kinetics of the synthesis of supercoiled and nonsupercoiled virus DNA was studied in chicken embryo fibroblasts (CEF) infected with the Schmidt-Ruppin strain of Rous sarcoma virus (RSV) for different times. Secondary cultures of CEF were infected with RSV at a multiplicity of infection (moi) of 1-5 focus-forming units/cell and with a transformation defective (*td*) derivative at a moi of 1-5 infectious units/cell. Infectivity of the nucleic acids (DNA, RNA, and DNA-RNA hybrid) purified from the CEF after 3-24 hr of virus infection was determined by a transfection assay. Infectious virus nucleic acids were detected at 6 hr after infection for both RSV and the derivative. Twenty-four hours after infection, much larger amounts of infectious unintegrated DNA were recovered: 1,500 IU of *td* virus DNA and 7,800 IU of RSV DNA. The hybrid fraction was also infectious 24 hr after infection. Infectious supercoiled DNA could be recovered at 16 hr after infection. The specific infectivity of the supercoiled DNA was less than that of the nonsupercoiled fraction. Approx 8%, 6%, and 25% of the infectious DNA molecules had a supercoiled conformation at 1, 2, and 10 days after infection. Infectious unintegrated virus DNA was recovered 10 days after infection. The transfection assay confirmed that <1 cell in 10²-10³ chronically infected cells contains an unintegrated infectious DNA molecule. (29 refs)

- 79-1546 Characterization of Some Isolates of Newly Recovered Avian Sarcoma Virus.** (Eng) Halpern, C. C. (Rockefeller Univ., New York, NY, 10021); Hayward, W. S.; Hanafusa, H. *J Virol* 29(1): 91-101; 1979.

The biological and biochemical characteristics of newly recovered avian sarcoma virus (rASV) isolated from tumors of chickens injected with transformation-defective (*td*) mutants of the Schmidt-Ruppin strain of Rous sarcoma virus (SR-RSV) were studied. High titers of rASV's were generally obtained by cocultivation of tumor cells with normal chicken embryo fibroblasts or by homogenization of tumor tissues. All rASV isolates tested belonged to the same subgroup (A) as that of the *td* viruses from which they were derived, and the *gag* gene of the rASV's appeared to be derived from the *td* virus. Most rASV's were nondefective, although several isolates recovered from chickens infected with one *td* mutant appeared to be defective in replication. Sucrose sedimentation data indicated that the rASV's from several *td* isolates contained genomic RNA that was the same size as that from SR-RSV-A but 300-500 nucleotides larger than that of the parental *td* RNA. An *src*-specific complementary DNA probe hybridized 7%-30% to RNA's from various *td* viruses and approx 95% to RNA's from two isolates of rASV. Thus, the generation of rASV from *td* viruses involves the acquisition of new *src*-specific information. The data strongly suggest that the generation of rASV involves a genetic interaction between *td* virus and host cell genetic information. (36 refs)

- 79-1547 Oligosaccharide Chains of Avian RNA Tumor Virus Glycoproteins Contain Heterogeneous Oligomannosyl Cores.** (Eng) Hunt, L. A. (Dept. Microbiology, Univ. Kansas Medical Center, Coll. Health Sciences and Hosp., Kansas City, KS, 66103); Wright, S. E.; Etchison, J. R.; Summers, D. F. *J Virol* 29(1): 336-343; 1979.

To study the oligosaccharide chains of avian tumor virus, pronase-digested glycopeptides from purified Prague strain Rous sarcoma virus subgroups B and C (PrB-RSV and PrC-RSV, respectively) were analyzed by gel filtration coupled with specific exoglycosidase (EG) and endo- β -N-acetylglucosaminidase D (EAGA) digestions. A large fraction of the glycopeptides from purified PrB-RSV was sensitive to the combined EG and EAGA digestion. The oligosaccharide chains on these glycosidase-sensitive glycopeptides were heterogeneous with respect to the size of their oligomannosyl cores, containing similar amounts of 3-mannose and 5-mannose structures. With the (2-³H)-mannose-labeled glycopeptides from PrC-RSV, most of the oligosaccharide chains were high-mol-wt acidic structures with similar numbers of 3-mannose and 5-mannose core structures. (32 refs)

- 79-1548 Is the Product of the *src* Gene a Promoter?** (Eng) Bissell, M. J. (Lab. Chemical Biodynamics, Lawrence Berkeley Lab., Univ. California, Berkeley, CA,

94720); Hatie, C.; Calvin, M. *Proc Natl Acad Sci USA* 76(1): 348-352; 1979.

The effect of treatment with the tumor promoter 12-O-tetradecanoylphorbol 13-acetate (TPA) was studied in normal primary avian tendon (PAT) cells and chicken embryo fibroblasts (CEF) and in PAT and CEF cells infected with a temperature-sensitive (*ts*) mutant of Rous sarcoma virus (RSV; LA24). 2-Deoxy-D-glucose (2-dGlc) uptake, collagen synthesis, and morphology were assessed as indicators of transformation. Addition of TPA to normal cells maintained at 41 C resulted in increased 2-dGlc uptake and a decreased collagen synthesis but the changes were smaller than those occurring after transformation. Addition of TPA to LA24-infected cells at 41 C (the nonpermissive temperature) produced changes that were close to or even more drastic than those in LA24-infected cells grown at 35 C. Morphologically, LA24-infected PAT cells at 41 C appeared entirely transformed by 10 hr. In a shift-down experiment, cells shifted in the presence of TPA for 12 hr were morphologically similar to cells that had been shifted to 35 C for 24-36 hr in the absence of TPA. Attempts to produce foci with LA24-infected cells at 41 C in the presence of TPA were unsuccessful. However, significant morphological alterations of LA24-infected CEF were produced in semisoft agar after 24 hr of treatment at 41 C. Under the same conditions, normal cells showed only an increase in criss-cross patterns. It is proposed that viral carcinogenesis occurs in two stages: an initiation step caused by the expression of a part of viral genome other than *src* and a promotion step caused by the activation of the *src* gene. The *src* gene product could be enhanced or replaced by other promoting agents. (39 refs)

- 79-1549 Effects of the *src* Gene Product on Microfilament and Microtubule Organization in Avian and Mammalian Cells Infected with the Same Temperature-Sensitive Mutant of Rous Sarcoma Virus.** (Eng) Wang, E. (Rockefeller Univ., New York, NY, 10021); Goldberg, A. R. *Virology* 92(1): 201-210; 1979.

The cytoskeletal organization was studied in rat kidney cells (RKC) and chick embryo fibroblasts (CEF) transformed by a temperature-sensitive (*ts*) *src* mutant (LA25) of Rous sarcoma virus (RSV). At the nonpermissive temperature (39.5 C), LA25-infected RKC displayed a well-defined network of actin-containing fibers that represented bundles of microfilaments of 50-70 A. Within 12-24 hr of shifting to the permissive temperature (33 C), > 95% of the actin fibers had disappeared from the cytoplasm. Their organization became unrecognizable and the cell shape was of the transformed phenotype. Microtubule organization, however, remained intact upon shifting from the nonpermissive to the permissive temperature. RKC transformed by RSV grew in soft agar and formed colonies at the permissive temperature. In LA25-infected CEF, both microfilament and microtubule organization was lost shortly after the shift to the permissive temperature. These results show that the LA25 *src* gene product can differentially affect the organization of microtubules

and microfilaments. It is possible that avian cells allow the synthesis of *src* gene product in sufficient amounts to cause considerable alterations in microtubular organization, whereas the level of *src* in rat kidney cells may not be sufficient to alter microtubule distribution. The results also suggest that the absence of microfilament bundle organization, but not necessarily microtubule organization, may be a factor in determining if a cell can grow in an unregulated fashion in an animal. 79-1553 On the Reduced Intercellular Adhesiveness of Virally Transformed BHK21 Cells. (Eng) Edwards, J. G. (Dept. Cell Biology, Univ. Glasgow, Glasgow G12 8QQ, Scotland); Dysart, J. M.; Edgar, D. H.; Robson, R. T. *J Cell Sci* 35: 307-320; 1979.

The intercellular adhesiveness of normal and virally transformed baby hamster kidney (BHK21) cells was compared under a variety of conditions. The cells were transformed by either polyoma or Rous sarcoma virus (RSV). In a long-term aggregation assay, cells were resuspended in complete growth medium and incubated in a gyratory shaker for 18-24 hr. The untransformed BHK21 clone 13 (C13) cells yielded firm spherical aggregates. The transformed cells aggregated much less than the C13 cells, and the aggregates that were formed appeared to be unstable. This difference could be measured by electronic particle counting or by filtering aggregated suspensions of ³²P-labeled cells through fabric filters of various pore sizes. The aggregation difference was not dependent on exposure to trypsin. The presence of ϵ -aminocaproic acid (10 mg/ml), an inhibitor of plasmin activation, during aggregation did not enhance the aggregation of transformed derivatives. BHK cells transformed by the Bryan strain of RSV aggregated in a short-term (45 min) assay but not in the

long-term assay. When suspended cells were seeded onto confluent sheets of cells of like type, none of the transformed lines showed a marked reduction, compared with C13 cells, in ability to adhere. The decreased aggregation of transformed cells in the long-term assay is consistent with suggestions that the large, external, transformation-sensitive (LETS) protein is involved in the intercellular adhesion of fibroblasts. It is suggested that the short-term aggregation of freshly trypsinized cells may depend on the secretion of LETS from an intracellular pool. (45 refs)

79-1554 Diamine Oxidase and Polyamine Oxidase Activities in Normal and Transformed Cells. (Eng) Quash, G. (Unité de Virologie Fondamentale et Appliquée, I.N.S.E.R.M.-U.51, Lyon Cedex 2, France); Keolouangkhot, T.; Gazzolo, L.; Ripoll, H.; Saez, S. *Biochem J* 177(1): 275-282; 1979.

The diamine oxidase activity of normal rat kidney cells and cells transformed by avian sarcoma virus was compared to determine whether there is a direct relationship between this activity and cell growth. For both cell types, diamine oxidase activity rose during the lag phase after seeding, was highest at 24 hr, and decreased during the exponential phase of growth. The activity in transformed cells was 50% greater than that in normal cells at 24 hr, was twofold lower at saturation density, and was three- to fourfold lower at confluence. The presence of free intracellular putrescine was not responsible for the difference. Differences of about the same order of magnitude were observed between transformed and normal human, chicken, and rat cells. Polyamine activity also varied with the growth of transformed rat kidney cells, but it showed no significant variation from normal between 24 and 96 hr after seeding. The activity in cells at confluence was three- to fivefold lower in the transformed cells than in the normal cells. A similar 5- to 10-fold decrease in activity was seen in 9,10-dimethylbenz(a)anthracene-induced rat mammary tumors and in human esophageal tumors. (27 refs)

79-1555 Decreased Production of Transforming Virus and Altered Antigenic Behaviour in Cultured Avian Sarcoma Cells. (Eng) Wainberg, M. A. (Lady Davis Inst. Medical Res., Jewish General Hosp., Montreal, Canada); Yu, M.; Israel, E. *J Gen Virol* 42(2): 255-264; 1979.

Transforming virus production and antigenic behavior were examined in cultured avian sarcoma cells derived from young birds carrying progressively growing sarcomas or from older animals carrying regressing neoplasms. Cultivated tumor cells from mature chickens that had been injected with avian sarcoma viruses (ASV) were defective in producing either transforming or oncogenic virus, but they sometimes synthesized incomplete physical particles, as measured by RNA-dependent DNA polymerase (RDDP) activity. Tumor cells derived from progressively growing neoplasms synthesized large quantities of fully transforming oncogenic progeny virus and RDDP. After varying periods of culture (25-30

days and 4-5 passages), production of both transforming virus and RDDP fell off dramatically. However, the long-term-cultured tumor cells remained fully oncogenic following injection into susceptible chickens, indicating that the genetic information needed to induce tumor growth continued in the absence of virus production. Supernatant fluids from freshly cultivated (3-4 days) tumor cells derived from regressing malignancies were unable to stimulate the lymphocytes of tumor-bearing chickens. Supernatant fluids from ASV-transformed chicken embryo fibroblasts or from cultures of tumor cells from progressing neoplasms were equally efficient as specific antigens. Following multiple passages and extended growth in culture, however, the ability of these tumor cell fluids to stimulate the lymphocytes of sensitized hosts diminished concomitantly with the capacity of these cells to synthesize progeny virus. Thus, tumor cells that are derived from progressively growing malignancies and that senesce in culture closely resemble tumor cells that have aged in vivo. (24 refs)

- 79-1556 Translation of Avian Sarcoma Virus RNA in *Xenopus laevis* Oocytes.** (Eng) Katz, R. A. (Dept. Microbiology, Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032); Maniatis, G. M.; Guntaka, R. V. *Biochem Biophys Res Commun* 86(2): 447-453; 1979.

Studies demonstrating the synthesis and posttranslational processing of Pr76 (a 76,000-dalton precursor protein to group-specific antigens p27, p19, and p12/15) after microinjection of avian sarcoma virus 35S subunits or aggregated 60S-70S virion RNA are presented. Bound transfer RNA-trp primer did not appear to affect the capacity of 35S virion RNA to direct protein synthesis. (20 refs)

- 79-1557 Further Study on the Three-Dimensional Structure of the Core of Marek's Disease Virus and Herpesvirus of Turkey.** (Eng) Okada, K. (Dept. Comparative Pathology, Faculty Veterinary Medicine, Hokkaido Univ., Sapporo, Japan); Fujimoto, Y.; Nakanishi, Y. H.; Onuma, M.; Mikami, T. *Arch Virol* 59(1/2): 137-144; 1979.

The three-dimensional structures of the cores of Marek's disease virus (MDV) and herpesvirus of turkeys (HVT) were examined with the use of a tilting apparatus attached to an electron microscope. Quail fibroblast cultures were infected with the JM strain of MDV and the FC 126 strain of HVT; the Cal-1 strain of MDV in a chick kidney cell culture was also used. Immature virus particles were found in the nuclei of the MDV- and HVT-infected cells. Numerous small nuclear particles and cross-shaped capsids were found in HVT-infected cells, and empty capsids, which appeared to lack cores, were seen in cells infected with either virus. Some capsids had cores consisting of crossed toroids surrounding a cylindrical mass. The toroids were 10-20 nanometers (nm) thick with an outside diameter of 68 nm. A semicircular toroid and a core with two toroids were also detected. En-

veloped particles of different sizes were found in the nuclear vesicles and endoplasmic reticulum. The cores of these particles and those of the naked capsids consisted of numerous electron-opaque bands 10-20 nm thick. It is possible that the pleomorphic structures of the core may represent developmental stages of the viruses. (11 refs)

- 79-1559 Mouse Mammary Tumor Virus Genes: Regulation of Expression by Glucocorticoids and Structural Analysis with Restriction Endonucleases.** (Eng) Ringold, G. M. (Dept. Biochemistry, Univ. California, San Francisco, CA, 94143); Cohen, J. C.; Ring, J.; Shank, P. R.; Varmus, H. E.; Yamamoto, K. R. *J Toxicol Environ Health* 4(2/3): 457-470; 1978.

The effects of treatment with glucocorticoid hormones (eg, dexamethasone: DEX) on the production of mouse mammary tumor virus (MMTV) in a mouse mammary tumor cell line (GR) and a rat hepatoma line (HTC) were studied. These cell lines contain specific glucocorticoid receptors detectable by the binding of ³H-DEX in whole cells or in cell extracts. DEX stimulated MMTV production. The reaction appeared to be a primary effect of the receptor-steroid complex, as a result of which the rate of synthesis of MMTV RNA was selectively increased. Viral RNA synthesis was stimulated 10-20 times in GR cells and at least 20 times in HTC cells. The rate of viral RNA synthesis reached a max within 15 min after addition of the hormone. The amount of MMTV DNA and the level of expression of these viral genes were determined in independently isolated clones of infected HTC cells by measuring the kinetics of annealing of ³H-MMTV complementary DNA to cell DNA or cell RNA. Although clones containing many copies of viral genes tended to produce more viral RNA in the presence of DEX than clones containing few MMTV DNA copies, this correlation was not a strict one. Of the clones examined, all that produced basal levels of MMTV RNA were stimulated to produce increased quantities by DEX; however, the extent of MMTV RNA induction by DEX varied greatly from clone to clone (50- to 1,000-fold) in a manner that had no apparent relation to the number of integrated viral genes. It is conceivable that not all of the integrated viral genomes are being transcribed to an equal extent in the absence of DEX and that not all of them are stimulated to an equal extent in its presence. Unintegrated MMTV DNA remaining in chronically infected HTC cells was used as substrate to investigate the chromosomal loci at which viral genes integrate. Treatment with nine restriction endonucleases indicated that there are many sites in cellular DNA into which MMTV DNA can integrate, and that these sites may be a determining factor for MMTV RNA synthesis. (37 refs)

- 79-1560 Endogenous Mouse Mammary Tumor Virus DNA Is Distributed Among Multiple Mouse Chromosomes.** (Eng) Morris, V. L. (Dept. Microbiology and Immunology, Univ. Western Ontario, London, Ontario N6A 5C1, Canada); Kozak, C.; Cohen, J. C.; Shank, P. R.; Jolicoeur, P.; Ruddle, F.; Varmus, H. E. *Virology* 92(1): 45-55; 1979.

The distribution of endogenous mouse mammary tumor virus (MMTV)-specific DNA in the genome of A/HeJ mice was examined with the use of molecular hybridization and restriction endonucleases to analyze DNA from mouse-hamster hybrid clones that segregate mouse chromosomes. MMTV DNA sequences were present on at least three separate pairs of mouse chromosomes. Chromosome pair 4 contained two copies of MMTV DNA. Four copies of MMTV proviral sequences were located within chromosome pair 15 and 17. An additional unit of viral DNA segregated independently, although its location is ambiguous. The results obtained by kinetic analysis of DNA extracted from the mouse-hamster clones are in reasonable agreement with the data obtained by restriction endonuclease analysis. These findings coupled with those from other reports imply that the endogenous proviruses were acquired by independent infections of the germ line of individual progenitor mice and have since segregated during the development of inbred strains. (35 refs)

- 79-1561 Simultaneous Production of Casein and Mammary Tumor Virus in Mouse Mammary Epithelial Cells Grown on Floating Collagen Gels.** (Eng) Enami, J. (Dept. Physiology, Dokkyo Univ. Sch. Medicine, Mibu, Tochigi 321 02, Japan); Yang, J.; Nandi, S. *Cancer Lett* 6(2): 99-105; 1979.

The simultaneous production of casein and mammary tumor virus (MTV) in response to hormones was analyzed in monolayer cultures of mammary epithelial cells from MTV-infected pregnant BALB/cfC3H mice. A comparison of the two cell culture substrata, plastic culture dishes and floating collagen gels, showed that the latter supported a much higher degree of simultaneous casein and MTV production in response to hormones. Among the three different combinations of hormones used, insulin alone, insulin + cortisol, or insulin + cortisol + prolactin, the latter stimulated max casein and MTV production in serum-free culture medium. The importance of the floating collagen gels was further shown by delaying the flotation of the gels. When the release of the gels was delayed, there were concomitant delays in the increase of casein and MTV production. These results indicate that hormones, the nature of the substratum, and flotation regulate the degree of differentiation of mammary epithelial cells in vitro. (18 refs)

- 79-1562 Phosphoproteins of the Murine Mammary Tumor Virus.** (Eng) Sarkar, N. H. (Memorial

Sloan-Kettering Cancer Center, New York, NY, 10021); Whittington, E. S.; Racevskis, J.; Marcus, S. L. *Virology* 91(2): 407-422; 1978.

To determine whether any of the structural components of murine mammary tumor virus (MuMTV) are phosphorylated, MuMTV labeled in vivo with [³²P]orthophosphate and ³H-amino acids was analyzed on cylindrical sodium dodecyl sulfate (SDS)-polyacrylamide gels. Of the five major polypeptides of MuMTV (gp47, gp34, p27, p16 and p12), ³²P comigrated to a great extent with p23 and to a lesser extent with p27. Further analysis by hydrophobic chromatography, gel electrophoresis, slab gel electrophoresis, and Bio-Gel A 5m chromatography identified p23 and p27 as phosphoproteins. Radioimmunoprecipitation indicated that p23 is not antigenically related to p27 and suggested that p23, although a minor protein component of MuMTV, is an independent entity and the major phosphoprotein of this virus. Both p27 and p23 contained phosphoserine, and some p27 preparations appeared to contain phosphothreonine. (33 refs)

- 79-1563 Structural Components of Mouse Mammary Tumor Virus. III. Composition and Tryptic Peptides of Virion Polypeptides.** (Eng) Yagi, M. J. (Dept. Neoplastic Diseases, Mount Sinai Sch. Medicine, 5th Ave. at 100th St., New York, NY, 10029); Tomana, M.; Stutzman, R. E.; Robertson, B. H.; Compans, R. W. *Virology* 91(2): 291-304; 1978.

The compositions and possible structural interrelationships among mouse mammary tumor virus (MMTV) proteins were examined following their isolation by preparative sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). Their tryptic peptides and glycopeptides were analyzed, and their amino acid and carbohydrate compositions were determined. The minimal carbohydrate content was 9.3% for gp52, 11.2% for gp37.7, and 19.4% for gp33. The carbohydrate moieties of all three glycoproteins were similar in composition, and they contained fucose, mannose, galactose, N-acetylglucosamine, and N-acetylneuraminic acid. One major size class of oligosaccharide side chain was generated from each glycoprotein by pronase digestion of gp52, gp37.7, and gp33. The mol wts of these glycoprotein size classes were 3,200-3,600 for gp52, 3,750-4,250 for gp37.7, and 3,200-3,700 for gp33. Tryptic peptide patterns of MMTV glycoproteins demonstrated that many of the peptides from gp37.7 and gp33 were similar in size and charge. However, comparison of the tryptic peptides of gp52 with those from gp37.7 and gp33 indicated that gp52 was not structurally related to the other two glycoproteins. SDS-PAGE profiles obtained after limited trypsin digestion of gp52, gp37.7, and gp33 resolved two carbohydrate-containing peptides from each glycoprotein, that appeared to be of similar size. Analyses of tryptic peptides of the five nonglycosylated MMTV proteins p46, p24, p17, p13, and p8 indicated that these proteins possess distinct amino acid sequences. (46 refs)

79-1564 Development of an Isotopic Staphylococcal Protein A Test for Detection of Cell Surface Mammary Tumor Virus Antigens (Meeting Abstract). (Eng) Callis, A. H. (Univ. Tennessee, Memphis, TN, 38163); Ritzl, E. M. *Fed Proc* 38(3, part 2): 911; 1979. (no refs)

79-1565 Localization of Murine Mammary Tumor Virus Polypeptides on the Surface of Tumor Cells. (Eng) Westenbrink, F. (Radiobiological Inst., TNO, Rijswijk, Netherlands); Koornstra, W.; Creemers, P.; Brinkhof, J.; Bentvelzen, P. *Eur J Cancer* 15(1): 109-121; 1979.

Antisera raised in rabbits against three of the major viral polypeptides of murine mammary tumor viral (MMTV), a glycoprotein with a mol wt of 52,000 daltons (gp52) and two polypeptides with a mol wt of 28,000 and 12,000 daltons (p28 and p12, respectively), were used to assay these viral constituents on the cell membrane. No significant cross-reactivity was detected among the three antisera by immunodiffusion, immunoelectrophoresis, and radioimmunoassay, indicating that the three MMTV components are immunologically unrelated. In a fixed-cell immunofluorescence assay using the three antisera, gp52, p28, and p12 were detected in the cytoplasm of murine mammary tumor cell lines Mm5mt/c1 and C3HMT/C111, as well as in the murine leukemia cell lines GRSL18 and L1210. No virus-specific fluorescence was observed in the mammary tumor line EMT-6, which does not release MMTV. The concentration of gp52 in the cytoplasm was considerably lower than that of p28 and p12. In the membrane immunofluorescence assay, only gp52 proved to be localized on the cell surface. In humoral cytotoxicity tests, only antiserum to gp52 gave positive reactions with Mm5mt/c1, L1210, and GRSL18. The serum did not react with BALB/3T3 cells infected with Rauscher murine leukemia virus. The prevalence of gp52 on the cell surface suggests that this antigen is the best candidate for future vaccination studies. (30 refs)

79-1566 Intracytoplasmic Type A Particles from Mammary Tumours and Leukaemias of Strain ICRC Mice. (Eng) Karande, K. A. (Biology Div., Cancer Res. Inst., Tata Memorial Centre, Parel, Bombay 400 012, India); Joshi, B. J.; Talageri, V. R.; Dumaswala, R. U.; Ranadive, K. J. *Br J Cancer* 39(2): 132-142; 1979.

The morphological, biophysical, immunological, and structural characteristics of intracytoplasmic A-type particles from ovarian hormone-induced leukemias of strain ICRC mice and mammary tumors of ICRC and C3H(Jax) mice were studied. The purified virions banded at a density of 1.20 g/ml in 12%-60% sucrose gradients after spinning at 113,000 g for 4 hr. Gel electrophoresis indicated that the A particles from mammary tumors contained seven to eight polypeptides ranging in size from 14,000 to 100,000 daltons, and that their leukemia A particles contained eight polypeptides ranging from 10,000 to 74,000 daltons. All bands were PAS-negative. Immunodiffusion and immunoelectrophoresis indicated that

the leukemia and mammary tumor A particles had common antigens and that three proteins of mouse mammary tumor virus were antigenically similar to those of A particles. Purified A virus preparations were inoculated into ICRC and DBA-MTI sucklings. One of 8 inoculated ICRC females and 2/10 control ICRC females developed breast adenocarcinomas, and 2 inoculated ICRC males developed leukemias. Of 6 inoculated DBA-MTI females, 1 developed leukemia, 1 developed a spleen tumor, and 1 developed a cervical tumor; DMBA-MTI males remained tumor-free. The ICRC mouse is a good model for studying hormone:viral interactions in carcinogenesis. (37 refs)

79-1567 Mechanisms of Leukemogenesis. I. Generation of Autoreactive Lymphocytes in Response to a Murine Leukemia Virus (Meeting Abstract). (Eng) Schenk, P. J. (Downstate Medical Center, Brooklyn, NY, 11203); Howe, M. L. *Fed Proc* 38(3, part 2): 1072; 1979. (no refs)

79-1568 Phenotypic Mixing Between Murine Leukemia Viruses: Characteristics of Ecotropic Virus Infection of Heterologous Cells. (Eng) Ishimoto, A. (Lab. Viral Diseases, NIH, Bethesda, MD, 20014); Hartley, J. W.; Rowe, W. P. *Virology* 91(2): 464-471; 1978.

Aspects of ecotropic murine leukemia virus (MuLV) infection of heterologous cells achieved by phenotypic mixing were studied. The nomenclature used for the different classes of virions is the genotype followed by the host range phenotype in parentheses; X = xenotropic, M = ecotropic. Both xenotropic [X(x)] and phenotypically mixed [M(x)] particles infected mink, rabbit, duck, guinea pig, human, and cat cells, but not chicken C/O cells. There was generally correspondence between the titers of M(x) and X(x) virions detected. Mink cell cultures inoculated with the M(x) pools showed XC plaques when subjected to the direct UV-XC plaque development assay. These plaques arose by proliferation of the cells infected in the first cycle of infection, and there was no evidence for XC-positive, mink-infectious competent virions in the preparation. Clonal lines of mink and rabbit cells chronically infected with N-tropic ecotropic (AKR-L1), B-tropic ecotropic (WN1802B), and NB-tropic ecotropic (Friend) MuLV were established. Virtually all cells produced virus but at a generally low rate. The infectivity titers were 1 to 3 log₁₀ lower than those obtained with ecotropic viruses in mouse cells or with xenotropic viruses in mink cells or in the rabbit corneal cell line SIRC. Also, the number of cells that registered positive by immunofluorescent staining with MuLV antiserum was generally low. These viruses showed ecotropism and the same *Fv-1* restriction patterns as the input viruses through more than 6-12 mo of chronic virus production in the heterologous cells. Treatment with 5-iododeoxyuridine enhanced virus production up to 10-fold in 3/4 lines tested and increased fluorescent antibody staining two- to fourfold in two lines. Dexamethasone treatment slightly increased virus production in two lines. The infected lines were

VIRAL CARCINOGENESIS

sensitive to superinfection with xenotropic MuLV and with feline leukemia virus. (20 refs)

- 79-1569 XenCSA: Cell Surface Antigens Related to the Major Glycoproteins (gp70) of Xenotropic Murine Leukemia Viruses.** (Eng) Morse, H. C. (Lab. Microbial Immunity, Natl. Inst. Allergy and Infectious Diseases, NCI, NIH, Bethesda, MD, 20014); Chused, T. M.; Boehm-Truitt, M.; Mathieson, B. J.; Sharrow, S. O.; Hartley, J. W. *J Immunol* 122(2): 443-454; 1979.

Antisera from rabbits immunized with xenotropic murine leukemia virus (MuLV)-infected rabbit corneal (SIRC) cells were tested for patterns of reactivity with thymocytes and spleen cells of inbred mouse strains. The antisera contained antibodies with class-specific reactivity for a set of gp70 molecules coded for by xenotropic MuLV. The antigens recognized by these sera were designated XenCSA for xenotropic MuLV envelope-related cell-surface antigens. Using flow microfluorometry, thymocytes and spleen cells from 63 strains of inbred mice showed a wide range of XenCSA expression that could be divided into three basic phenotypic patterns: high XenCSA expression on both thymocytes and spleen cells (19 strains); low expression on thymocytes but high expression on spleen cells (17 strains); and low expression on both cell populations (27 strains). Expression of XenCSA was highly correlated with expression of G-IX on thymocytes, but it was not correlated with expression of Fv-1, T1a, H-2, Pca-1, or Gross cell-surface antigen. The level of XenCSA expression was also independent of the amount of infectious xenotropic MuLV produced by the cell. An antigen related to XenCSA was found to circulate in the serum of some but not all strains of mice expressing the cell-surface antigen. The data indicate that antigens related to the gp70 of xenotropic MuLV are a normal surface constituent of lymphocytes from all inbred mouse strains. (63 refs)

- 79-1570 RNA Sequencing Provides Evidence for Allelism of Determinants of the N-, B- or NB-Tropism of Murine Leukemia Viruses.** (Eng) Rommelaere, J. (Dept. Biology, Center Cancer Res., Massachusetts Inst. Technology, Cambridge, MA, 02139); Donis-Keller, H.; Hopkins, N. *Cell* 16(1): 43-50; 1979.

Three large RNase T1-resistant oligonucleotides (ON's) previously shown to be genetically associated with either the N-, B-, or NB-tropism of C-type murine leukemia viruses of BALB/c origin were sequenced. The three ON's, which lie in the 5' third of the ON maps of their respective viruses, were found to share a 10-base sequence. These observations suggest that the determinants of N-, B-, or NB-tropism monitored by the three ON's are allelic. The ON's associated with N- and B-tropism differed in sequence at 4/16 nucleotides, but the B- and NB-tropism-associated ON's differed in sequence by only 1/16 bases. These results are consistent with the possibility that B-tropic viruses arise from N-tropic viruses by recombination, but NB-tropic viruses arise from

B-tropic viruses by mutation. Two T1 ON's, designated 12 and 35, that comigrate with the N and B ON's, respectively, in two-dimensional gel electrophoretic fingerprints of N- and B-tropic viruses, were also sequenced. ON's 12 and 35 are present in the N-, B- and NB-tropic viruses of BALB/c origin that were analyzed. ON's N and 12 shared 10 bases of their sequence, although these were not the same 10 bases shared by the three tropism ON's. The possible significance of this sequence repetition in the N and 12 ON's, which lie in opposite thirds of the genome, is not known. (24 refs)

- 79-1571 Chronic Blastogenesis of Endogenous Viral Antigen(s): A Possible Mechanism for C-Type Viral Leukemogenesis (Meeting Abstract).** (Eng) Lee, J. C. (Cancer Biology Program, NCI, Frederick Cancer Res. Center, Frederick, MD, 21501); Ihle, J. N. *Fed Proc* 38(3, part 2): 1451; 1979. (1 ref)

- 79-1572 Cytotoxic Murine T Cells Directed Against AKR/Gross Virus-induced Tumors (Meeting Abstract).** (Eng) Green, W. R. (Fred Hutchinson Cancer Res. Center, Seattle, WA, 98104); Nowinski, R. C.; Henney, C. S. *Fed Proc* 38(3, part 2): 1466; 1979. (no refs)

- 79-1573 The Nature of the Association Between the Murine Leukemia Virus Envelope Proteins.** (Eng) Pinter, A. (Sloan-Kettering Inst. Cancer Res., 1275 York Ave., New York, NY, 10021); Lieman-Hurwitz, J.; Fleissner, E. *Virology* 91(2): 345-351; 1978.

The amount of gp70 and p15(E), the two major murine leukemia virus (MuLV) envelope proteins, present as a disulfide-linked complex ([gp90]) was assayed for several MuLV preparations. Upon dissociation of AKR MuLV with 1% sodium dodecyl sulfate (SDS) under nonreducing conditions, approx 10% of the gp70 molecules were found in the form of [gp90]; disruption with 0.5% Nonidet P-40 (NP-40) prior to addition of SDS increased this percentage to 39%. For Rauscher MuLV, [gp90] was not observed after disruption directly with SDS; upon incubation with NP-40 prior to SDS treatment, increasing amounts of the complex were formed. Pretreatment with iodoacetamide did not inhibit the subsequent formation of [gp90] in the presence of NP-40. Exposure of virions to the thiol-specific reagents 2,2'-dithiobis(m-nitropropyridine) or N-ethylmaleimide resulted in quantitative conversion of gp70 to [gp90]. When these latter reactions were used to test for the noncovalent association of gp70 and p15(E), it was demonstrated that the two proteins maintained their native association in the presence of 0.5% NP-40, both in high- and low-salt concentrations. These results indicate that (1) a stable, intermolecular disulfide-linked gp70-p15(E) complex can form spontaneously after disruption of virions with nonionic detergents, and after activation of sulfhydryl groups of the membrane proteins and (2) the complex is not present in large quantities in the intact virions. (19 refs)

- 79-1574 Selective Packaging of Host tRNA's by Murine Leukemia Virus Particles Does Not Require Genomic RNA.** (Eng) Levin, J. G. (Lab. Molecular Genetics, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD, 20014); Seidman, J. G. *J Virol* 29(1): 328-335; 1979.

The role of genomic RNA in transfer RNA (tRNA) selection was studied by comparing the composition of free 4S RNA in normal murine leukemia virus (MuLV: strains AKR-L1 and Moloney) and actinomycin D (A-D: 0.1 µg/ml)-treated virions, which lack genomic RNA (A-D virions). Although the A-D and normal virions contained approx the same amounts of RNA per virion, the 70S/4S ratio of the normal virions was eightfold greater than that of the less infective A-D virions. Virtually all of the 4S RNA in cell preparations of normal and A-D virions was contained within the virus particles. Normal and A-D virions contained the same population of tRNA's and in similar proportions, which suggests that the tRNA composition of MuLV particles is not determined by the viral RNA genome. Oligonucleotide fingerprinting of normal and A-D virion RNA revealed an identical spot that closely corresponded to the published fingerprint for Moloney MuLV tRNA-Pro. A possible role for one or more viral proteins, including reverse transcriptase, is suggested. (58 refs)

- 79-1575 Interactions of Murine Leukemia Virus (MuLV) with Isolated Lymphocytes. IV. The Role of Mitogen-induced Cellular DNA Synthesis in Virus Infection and Replication.** (Eng) Cerny, J. (Dept. Microbiology, Harvard Univ. Sch. Public Health, Boston, MA, 02115); Isaak, D. D. *Int J Cancer* 23(2): 260-268; 1979.

The requirement for lymphocyte (LC) activation with mitogen during in vitro infection with murine leukemia virus (MuLV) of Friend virus complex (FV) and the suppressive effects of MuLV on mitogen-induced LC activation were studied in short-term suspension cultures. LC's were infected with FV and then resuspended in medium with or without mitogens. Cells releasing infectious MuLV were enumerated as infectious centers (IC) on sarcoma virus +, leukemia virus-fibroblasts. The accumulation of IC followed a biphasic curve characterized by a plateau between days 1 and 4 and by a 10-fold increase in IC between days 5 and 7. Stimulation with a B-cell mitogen, bacterial lipopolysaccharide (LPS), following infection increased the number of IC 10- to 40-fold. Stimulation with a T-cell mitogen, concanavalin A (Con A), did not appreciably increase the number of IC on day 5 postinfection. In addition, there was a comparable enhancement of IC in cultures stimulated with LPS 2 days prior to or immediately after FV infection and in those not stimulated until 2 days after infection. Treatment of FV-infected, LPS-stimulated LC's with 5,6-bromodeoxyuridine (BUdR) and visible light at 2 days abolished cellular DNA and RNA synthesis but did not diminish subsequent MuLV replication; however, cellular DNA and RNA synthesis as well as MuLV replication were inhibited in LPS-stimulated cells treated

with BUdR and light prior to FV infection. The uptake of ³H-thymidine and ¹⁴C-uridine by LPS-stimulated LC's was inhibited by about 50% in the presence of infectious FV, whereas uptake in Con A-stimulated LC's was not inhibited. The inhibition of LPS stimulation was not detectable until 24 hr and later; the uptake of ³H-thymidine during the first 12 hr after infection and mitogen activation were the same in infected and noninfected cultures. The results indicate that MuLV-Friend infects normal B cells but that subsequent virus replication and secondary infection remain low unless the cells are activated with a mitogen. Virus replication, however, eventually becomes independent of cellular DNA synthesis, and the virus itself inhibits cellular nucleic acid synthesis at a later stage in the infection. (37 refs)

- 79-1576 Changes in the Transplantability of a Virus-induced Murine Leukemia Tumor.** (Eng) Portis, J. L. (Rocky Mountain Lab., Natl. Inst. Allergy and Infectious Diseases, NIH, Hamilton, MT, 59840). *J Natl Cancer Inst* 62(3): 611-617; 1979.

A study was made of the unstable sc growth potential (GP) of a Friend virus-induced murine leukemia cell line (FBL-3) passaged in ascites form. The GP was found to change, depending on the interval of time spent in the peritoneal cavity. Sc injection of the original stock of FBL-3 (grown continuously in vitro) into C56BL/10 mice produced transient tumors that were uniformly rejected by days 20-40. The tumor cells passaged in ascites form for 7 days behaved like the in vitro-grown cells, whereas ascites cells harvested at 14 days produced progressive lethal sc tumors in 50%-70% of the recipients. The results were similar in C57BL/6 mice. The change in sc growth was reversible simply by altering the ascites passage schedule. Day 7 ascites cells (regressors) were converted to progressors by ip passage for 14 days, and day 14 ascites cells (progressors) were converted to regressors by ip passage for 7 days. The difference in GP between day 7 and day 14 ascites cells was not due to effects of nonneoplastic host cells accompanying the tumor cells in the ascites population, because neither dilution of nonneoplastic cells by in vitro culture nor selective killing of *H-2a/b* host cells by anti-*H-2* serum and complement altered the sc growth behavior of either day 7 or day 14 ascites cells. These results indicate that the change in the GP of FBL-3 occurred at the level of the tumor cells. However, no quantitative differences were observed in the expression of serologically detectable tumor-associated antigens by these two populations. Possible mechanisms for this change in transplantability are considered. (14 refs)

- 79-1577 Identification of a Non-*H-2* Gene (*Rfv-3*) Influencing Recovery from Viremia and Leukemia induced by Friend Virus Complex.** (Eng) Chesebro, B. (Rocky Mountain Lab., Natl. Inst. Allergy and Infectious Diseases, Hamilton, MT, 59840); Wehrly, K. *Proc Natl Acad Sci USA* 76(1): 425-429; 1979.

VIRAL CARCINOGENESIS

Two congenic backcross mouse generations (B10.A x A/WySn)_{F₁} x A/WySn and (C57BL/10 x A.BY)_{F₁} x A.BY, in which genes other than *H-2* were segregating, were examined to study recovery from Friend virus complex (FV) viremia independently of the *H-2* effect on recovery from leukemia. The dominant C57BL/10 allele of a single, autosomal, non-*H-2* gene (*Rfv-3*) was found to be required for recovery from viremia and leukemia induced by FV in *H-2b/b* mice. In *H-2a/a* mice, the *Rfv-3* gene apparently influenced recovery from viremia in the presence of persistent leukemia, because these mice lacked the appropriate *H-2* genotype for recovery from leukemia. The *Rfv-3* gene was distinct from the *Fv-2* gene, because recovery from viremia was seen in recombinant-inbred mice with the *Fv-2s/s* genotype. Furthermore, backcross studies indicated that *Rfv-3* and *Fv-2* were not linked. The *Rfv-3* gene may act by influencing the specific anti-FV humoral antibody response. (28 refs)

Strain XVII mice with various hematological types of Graffi virus-induced leukemia showed a pronounced thrombocytopenia (TCP) that was severe in the erythroblastic type and milder in the lymphatic types. The thrombocytic reactions that shortly followed Friend and Rauscher virus infection and occurred 3 wk after birth in AKR mice were not found with the the Graffi virus. A significant preleukemic TCP occurred 8 wk after Graffi virus infection in AKR mice. In neonatal (XVII x AKR)_{F₁} hybrids treated with N-nitroso-N-methylurea (NMU), the number of thrombocytes declined after manifestation of leukemia. An unexpected preleukemic TCP similar to that following viral leukemogenesis developed after NMU treatment. The possible cooperation of oncogenic viruses in chemical carcinogenesis is considered. 79-1583 Immunocytochemical Localization of gp70 over Virus-related Submembranous Densities in ts Mutant Rauscher Murine Leukemia Virus-infected Cells at the Nonpermissive Temperature. (Eng) Yeager, H. (Dept. Anatomy (Histology), Univ. Toronto, Toronto, Ontario, Canada M5S 1A8); Kalnins, V. I. *Virology* 91(2): 489-492; 1978.

An indirect immunocytochemical labeling technique employing goat antibody bound to colloidal gold particles as a marker was used to study the distribution of the major viral glycoprotein gp70 on surfaces of NIH/3T3 cells and virus in cultures infected with wild-type and mutant *ts29* Rauscher murine leukemia virus. When *ts29*-infected cells grown at the nonpermissive temperature (37°C) were treated with goat anti-gp70, the cell membranes over the submembranous densities were heavily labeled. When these cultures were shifted to a lower temperature, the amount of submembranous density was markedly reduced and a large number of early budding virus particles appeared. These particles also showed heavy labeling after treatment with goat anti-gp70. Relatively few gold particles were found over areas where submembranous densities or budding virions were absent, although the degree of labeling was above that seen in similar cultures treated with normal goat serum. The findings are consistent with the view that structural protein-membrane-glycoprotein interactions are important in C-type virus assembly. (9 refs)

79-1584 Association of Mouse Major Histocompatibility and Rauscher Murine Leukaemia Virus Envelope Glycoprotein Antigens on Leukaemia Cells and Their Recognition by Syngeneic Virus-Immune-Cytotoxic T-Lymphocytes. (Eng) Zarling, D. A. (Immunobiology Res. Center, Univ. Wisconsin, 1150 University Ave., Madison, WI, 53706); Keshet, I.; Watson, A.; Bach, F. H. *Scand J Immunol* 8(6): 497-508; 1978.

The physical association between the Rauscher murine leukemia virus (R-MuLV) envelope glycoprotein gp70 and the serologically defined mouse major histocompatibility antigen (H-2D) on the surface of R-MuLV-transformed C57BL/6 (H-2b; RBL-5A) cells was studied. The H-2b and R-MuLV gp70 proteins were independently precipitated from detergent-solubilized RBL-5A membrane protein extracts by

R-MuLV and H-2b antisera. Patching and capping experiments indicated that H-2Db and MLV gp70 antigens on RBL-5A cells form a specific mobile unit and redistribute together, therefore having a close topological relationship on the plasma membrane. H-2Db antigens appeared to be specific target molecules from syngeneic R-MuLV-immune cytotoxic T lymphocytes. α H-2Db sera, but not α H-2Kb sera, were highly effective in blocking T-lymphocyte-mediated lysis of RBL-5A cells; high-titer α R-MuLV gp70 sera had no effect. (32 refs)

- 79-1585 Murine Leukemia Virus gag Polyproteins: The Peptide Chain Unique to Pr80 is Located at the Amino Terminus.** (Eng) Schultz, A. M. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Oroszlan, S. *Virology* 91(2): 481-486; 1978.

The gag gene-encoded precursor polyproteins Pr80gag and Pr65gag of Rauscher leukemia virus were analyzed by chemical fragmentation, by immune precipitation with antisera specific to viral structural proteins, and then by one-dimensional peptide mapping. Cyanogen bromide fragmentation yielded two fragments common to both polypeptides: a fragment of 16,000-18,000 daltons (16K-18K); and a fragment of 46K. A fragment of 18K-20K occurred only in Pr65gag, and another peptide of 32K-34K was found only in Pr80gag. Fragmentation with 70% formic acid without cyanogen bromide yielded one major fragment of 46K common to both polyproteins, a fragment of approx 20K from Pr65gag, and a fragment of 33K from Pr80gag. The results suggest that Pr80gag is composed of Pr65gag and a 13K-15K peptide chain attached to the amino-terminus of Pr65gag. The carboxyl ends of the two polyproteins may be identical. (19 refs)

- 79-1586 A Murine Leukemia Virus Mutant with a Temperature-sensitive Defect in Membrane Glycoprotein Synthesis.** (Eng) Ruta, M. (Dept. Biochemistry, Sch. Medicine, Univ. Oregon Health Sciences Center, Portland, OR, 97201); Murray, M. J.; Webb, M. C.; Kabat, D. *Cell* 16(1): 77-88; 1979.

NIH/3T3 mouse cells infected with a temperature-sensitive mutant (ts-26) of Rauscher murine leukemia virus (R-MuLV) or with wild-type virus were labeled with 35 S-methionine, and cell extracts were examined for radioactive polypeptides by precipitation with monospecific antisera to viral proteins. When shifted from the permissive (31 C) to the nonpermissive (39 C) temperature, cells infected with ts-26 rapidly accumulated gPr90env, the glycoprotein precursor to the membrane envelope glycoprotein gp70 and to the membrane-associated protein p15E. At the same time, formation of these mature virion proteins stopped. Lactoperoxidase-catalyzed surface labeling with 125 I-iodine indicated that the plasma membrane of ts-26-infected cells became depleted of gp70 at 39 C. However, at 39 C these cells released defective MuLV's that lacked gp70 and p15E but contained an outer membrane. The released particles also contained an

aberrantly processed form of the major virion core protein p30. Many of these virion cores had an unusual immature, crescent shape. A previous report that cells infected with ts-26 process a 65,000-dalton precursor (Pr65gag) of the virion core proteins more slowly at 39 C than do cells infected with wild-type virus was confirmed, but the effect is relatively small. The amount of Pr65gag was approx 1.7 times higher in ts-26-infected cells than in wild-type virus-infected cells, whereas the concentration of fully processed p30 was reduced severalfold. It is proposed that a primary temperature-sensitive mutation in ts-26 occurs in its env gene and that the defect in Pr65gag processing is probably a secondary consequence of altered virion morphogenesis. (66 refs)

- 79-1587 Chemical Characterization of Rauscher Leukemia Virus Proteins.** (Eng) Brouwer, J. (Pathology Lab., State Univ. Leiden, Wassenaarseweg 62, Leiden, Netherlands); Pluijms, W. J.; Warnaar, S. O. *J Gen Virol* 42(2): 415-421; 1979.

Rauscher murine leukemia virus (R-MuLV) proteins were characterized by amino acid (AA) analyses and by mol wt determinations using gel filtration on cross-linked Sepharose 6B in 6 M guanidine HCl, and the results were compared with those for Moloney MuLV (M-MuLV) proteins. Two methods were used to isolate the proteins. When they were extracted from pelleted R-MuLV with buffer containing 0.4 M KCl and 1% Nonidet P40, 99.5% of the total protein was solubilized. Upon gel filtration, proteins gp70, p30, p15, and p12 were recovered as homogeneous fractions; the fraction containing p10 was slightly contaminated with p12. The chromatographic pattern obtained by gel filtration of a sample containing all the material present in a preparation of R-MuLV, including lipid and nucleic acid (method 2), was similar except that a homogeneous fraction of p10 was also obtained and contaminating proteins were present in the gp70 fraction. Mol wts of 56,000, 29,000, 15,000, 10,500, and 7,600 were found for gp70, p30, p15, p12, and p10, respectively. The two preparations of each protein gave identical results upon AA analysis. The sum of the percentages of met, phe, cys, leu, ile, val, trp, and his was taken as an index of hydrophobicity (HPB), and the order of HPB was p12E > 15, gp70 > p30 > p12, p10. p15 was the most hydrophobic of the gag gene-coded proteins. The AA compositions of the p10 and p30 polypeptides of R-MuLV and M-MuLV were very similar; the AA compositions of the p15 polypeptides were also similar, but not to the same extent. In contrast, the AA compositions of the p12 polypeptides differed considerably. These findings are expected from immunological data. (29 refs)

- 79-1588 Subcellular Distribution of Newly Synthesized Virus-specific Polypeptides in Moloney Murine Leukemia Virus-infected Cells.** (Eng) Shanmugam, G. (Dept. Biochemistry, Madurai Univ. Sch. Biological Sciences, Madurai 625021, India). *J Virol* 29(1): 385-389; 1979.

The newly synthesized virus-specific proteins present in the microsomal and postmicrosomal supernatant fractions of Moloney murine leukemia virus (MLV)-infected high-passage Swiss mouse embryo cells were studied by immune precipitation techniques. Anti-p30 serum precipitated five polypeptides (Pr88-gag, Pr72-gag, Pr62-gag, Pr39-gag, and p30) and anti-gp70 serum precipitated one polypeptide, Pr84-env. Most of the gag gene products were distributed in similar amounts in the microsomal and postmicrosomal supernatant fractions, whereas the envelope gene products were present predominantly in the microsomal fraction. A major proportion of p30 and its precursor intermediate Pr39-gag were also associated with the microsomal fraction. The data are consistent with the notion that the microsomal membrane fraction may play an important role in the replication of RNA tumor viruses. (25 refs)

- 79-1589 Antigenic Specificities of the Cellular Immune Response of C57BL/6 Mice to the Moloney Leukemia/Sarcoma Virus Complex.** (Eng) Enjuanes, L. (Cancer Biology Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Lee, J. C.; Ihle, J. N. *J Immunol* 122(2): 665-674; 1979.

The antigenic specificities of the cellular immune response against Moloney murine leukemia helper virus-Moloney sarcoma virus (MoLV-MSV)-induced tumors in C57BL/6 mice were studied using a variety of purified MoLV proteins. T-cell proliferation was directed primarily against the MoLV envelope glycoprotein gp71 and to a lesser extent against the MoLV protein p12. No blastogenic responses were detected against p10, p15, or p30. Blastogenesis was dependent on the presence of T cells but not rigidly dependent upon the presence of macrophages. There was no correlation in the relative magnitude of responses of individual mice to gp71 and p12. In microcytotoxicity assays using transformed nonproducer and producer cell lines with various virus serotypes. T-cell-mediated cytotoxicity in MoLV-MSV-infected mice was directed against MoLV gp71 and was not associated with the defective transforming virus. Antigen blocking experiments demonstrated that only MoLV gp71 could significantly block cytotoxicity (> 80%), which suggests that the major cytotoxic response was directed against MoLV gp71. Cell-mediated cytotoxicity was 10-12 days postinoculation, after the tumor had reached its peak size, and was no longer detectable by 25 days, when the tumor had regressed. The blastogenic response was biphasic: the first peak in reactivity was roughly comparable to the cytotoxicity pattern; the second peak was approx 50 days, after which it slowly declined. (29 refs)

- 79-1590 A Defined Subgenomic Fragment of In Vitro Synthesized Moloney Sarcoma Virus DNA Can Induce Cell Transformation upon Transfection.** (Eng) Andersson, P. (Fibiger Lab., DK-2100 Copenhagen 0, Denmark); Goldfarb, M. P.; Weinberg, R. A. *Cell* 16(1): 63-75; 1979.

DNA was synthesized in vitro by endogenous reverse transcription in detergent-permeabilized Moloney murine sarcoma virus (Mo-MSV) virions [clone G8-124, which contains a minimum of helper Moloney murine leukemia virus (Mo-MLV)]. In the absence of actinomycin D, the longest DNA molecules synthesized were double-stranded DNA (dsDNA) molecules of 5.8 kilobase pairs (kbp). A physical map of the positions of the cleavage sites for a series of restriction endonucleases was derived for this 5.8-kbp DNA after purification through neutral sucrose gradients. Mo-MSV DNA synthesized in vitro induced morphological transformation of MLV-infected and uninfected NIH-3T3 mouse fibroblasts upon transfection. The foci had a morphology indistinguishable from that of Mo-MSV-induced foci, and the induced transformed phenotype was stable. Gel-purified, restriction endonuclease-generated fragments of 5.8-kbp dsDNA containing the region from 2.8 to 4.9 kbp on the physical map of Mo-MSV DNA also induced foci, but endonuclease-generated DNA fragments lacking this region did not. When transformants derived by transfection with 5.8-kbp dsDNA were infected with Mo-MLV helper virus, Mo-MSV was rescued from a small portion of these cells, suggesting the establishment of the complete viral genome. The Mo-MSV DNA fragment spanning 2.8-4.9 kbp on the physical map represents the max estimate for the size of the transforming region of the Mo-MSV genome. This fragment includes the Mo-MSV sequences that are found in the DNA of uninfected mouse cells. It is speculated that the transforming function of Mo-MSV may be specified by nucleotide sequences that are totally of mouse cell or endogenous viral origin. (36 refs)

- 79-1591 Immunologic Regulation of Virally-induced Leukemogenesis by the Thymus (Meeting Abstract).** (Eng) Reinisch, C. L. (Div. Tumor Immunology, Sidney Farber Cancer Inst., Boston, MA, 02115); Kurtz, S. *Fed Proc* 38(3, part 2): 1466; 1979. (no refs)

- 79-1592 Role of Glycoconjugates in Expression of the Transformed Phenotype.** (Eng) Steiner, S. (Dept. Virology, Baylor Coll. Medicine, Houston, TX, 77030); Via, D.; Klinger, M.; Larriba, G.; Sramek, S.; Laine, R. *ACS Symposium Series* 80: 378-403; 1978.

Changes in fucose metabolism in murine sarcoma virus-transformed cells compared with that in normal cells were studied. These studies initially focused on the low-mol-wt, organic-extractable fucosylated components. The aminoacyl fucosides have been observed in all normal mammalian cell lines thus far examined. These components, FL3a (threonine and fucose), FL3b (serine and fucose), FL4a (threonine, fucose, and glucose) and FL4b (serine, fucose and glucose), appear to be a novel series of compounds with fucose O-glycosidically linked to amino acid. Glucose appears to be the terminal sugar in FL4a. There was a marked decrease in the incorporation of radioisotopically labeled fucose into FL4a in a variety of oncogenically transformed cells. The level of FL4a also

appeared to vary as a function of the expression of the transformed morphological phenotype. There was a glycoprotein(s) in which fucose appeared to be O-glycosidically linked to amino acid. The results of pulse studies with ^3H -fucose were consistent with the fucoprotein(s) being a precursor of FL4a. (19 refs)

- 79-1593 Revertants of Mouse Cells Transformed by Murine Sarcoma Virus. V. Loss of MSV-Specific Nucleotide Sequences from Cellular RNA.** (Eng) Nomura, S. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014). *Virology* 91(2): 444-452; 1978.

To investigate the mechanism of reversion in Moloney murine sarcoma virus (M-MSV)-transformed 3T3 cells [sarcoma-positive, leukemia-negative (S+L-) cells], cellular RNA and DNA were hybridized with total complementary DNA (cDNA) or MSV-specific cDNA derived from the M-MSV genome. Two types of revertants were obtained: flat, S- (rescue-negative), p30-positive revertants and a morphological revertant that differed from the parental cells only in that it was flat. Murine leukemia virus (MuLV) p30 determinants were expressed in most revertants, and the S+L- revertant cellular RNA's hybridized with unfractionated MSV (feline leukemia virus) cDNA. Using MSV-specific cDNA, it was demonstrated that MSV-specific viral RNA was absent from the S- revertants. However, the sequences homologous to MSV-specific cDNA were found in all revertant cellular DNA's, and they were quantitatively and qualitatively indistinguishable from those in the parental S+L- cells. The data indicate that only cells that retained rescuable MSV genomes contained MSV-specific viral RNA, irrespective of the cellular phenotype. By inference, sequences common to M-MSV and M-MuLV viral RNA contained at least part of the *gag* gene. M-MSV-specific nucleotide sequences were present, however, in DNA's both from revertants and S+L- cells, suggesting that either restriction in transcription of the viral genome or in processing of viral RNA sequences is responsible for S- revertants from S+L- cells. (41 refs)

- 79-1594 Studies of a Large Transformation-increased Membrane Protein in the BHK21 Cell System.** (Eng) Lage-Davila, A. (Instituto Nacional de Oncologia y Radiobiologia, 29 y E Vedado, Havana, Cuba); Montagnier, L. *Biochim Biophys Acta* 550(3): 435-449; 1979.

A 177,000-dalton (177K) plasma membrane protein that is significantly increased in baby hamster kidney (BHK21/13) cells transformed by hamster sarcoma virus was characterized by solubilization, cross-linking, metabolic labeling, and enzymatic radioiodination experiments. Electrophoretic analysis of the plasma membrane fractions from both transformed and untransformed BHK cells revealed a set of 18 major polypeptides (mol wt 50K-300K) whose presence and relative proportions were highly reproducible. The data showed that the 177K protein is: (1) a product of cellular metabolism because it could be labeled with ^{35}S -methionine;

(2) a membrane protein because it copurified with known plasma membrane fractions and with external iodine label; (3) probably a glycoprotein because it comigrated with a ^{14}C -glucosamine band upon gel electrophoresis; (4) partially exposed, because it could be iodinated externally by the non-penetrating lactoperoxidase reaction and because this label was trypsin-sensitive; and (5) an integral membrane protein, because it could only be solubilized in the presence of detergents and SH-reducing agents. The protein could be cross-linked and made to disappear rapidly from electrophoretograms after SH oxidation catalyzed by o-phenanthroline- CuSO_4 , which indicates that it is probably an SH-containing protein. Thus, 177K can be characterized as an integral membrane glycoprotein that is partially exposed at the outer cell surface. Data on several other membrane proteins of untransformed and transformed BHK cells are included. (19 refs)

- 79-1595 Evidence for Antigenic Determinants Shared by the Structural Polypeptides of (Shope) Rabbit Papillomavirus and Human Papillomavirus Type 1.** (Eng) Orth, G. (Unite de Recherches sur l'Étiologie Virale des Cancers Humains, Institut Gustave-Roussy, 94800, Villejuif, France); Breitburd, F.; Favre, M. *Virology* 91(2): 243-255; 1978.

Sera containing anti-(Shope) rabbit papillomavirus (RPV) antibodies were collected from 10 Vx7 carcinoma-bearing rabbits and used to study common antigenic determinants on RPV and human plantar wart papillomavirus type 1 (HPV-1). Seven of the 10 sera gave positive staining when tested by indirect immunofluorescence on human plantar wart sections. Staining with fluorescein-conjugated IgG from the serum with the highest antibody titer (Vx7-R221) showed that cross-reacting antigens were localized in the nuclei of the keratinizing cells and in keratinized cells in which HPV-1 capsid antigens were detected in an adjacent section using fluorescein-conjugated anti-HPV-1 virion IgG. The amount of cross-reacting antigen was lower than that of viral capsid antigen. For Vx7-R221 serum, cross-reacting antibodies were raised against an antigenic determinant(s) borne by viral structural polypeptides and masked in intact particles. Vx7-R221 serum precipitated mainly the 54,000-dalton HPV-1 polypeptide; ie, the capsomere subunit. Anti HPV-1 polypeptide sera contained antibodies against both HPV-1 antigens and RPV antigens, as detected by immunofluorescence. One of the cross-reactive Vx7 sera (Vx7-R337) gave a precipitin line continuous with that given by an anti-HPV-1 virion antiserum when tested by immunodiffusion using HPV-1 virions as antigens. This was also observed with 4/110 additional Vx7 sera tested. The results indicate that two kinds of antigenic determinants are shared by RPV and HPV-1 structural polypeptides: some are masked in intact particles and others are located on the virion surface but in a form usually unable to elicit antibody formation. stract). (Eng) Lubiniecki, A. S. (Melo Lab., Inc., Springfield, VA, 22151); Szakal, A. K. *Fed Proc* 38(3, part 2): 1450; 1979. (no refs)

79-1597 Morphological Evidence for the Presence of the Endogenous Guinea-Pig Retrovirus in the Lymphoblasts of L2C Leukemia. (Eng) Perk, K. (Dept. Animal Science, Hebrew Univ. Jerusalem, Rehovot Campus, P.O.B. 12, Rehovot, Israel); Dahlberg, J. E. *Experientia* 35(1): 104-105; 1979.

Blood samples from guinea pigs with L2C leukemia were examined for guinea pig virus (GPV) particles. Only during the terminal stages of the disease did L2C leukemic cells show virus particles indistinguishable from tissue-cultured GPV. Extracellular virus particles and intracytoplasmic A particles were frequently observed, but budding particles were rare. All of the budding particles observed contained completely formed nucleoids. The morphologic evidence for the presence of a B-type retrovirus in the late stages of leukemogenesis indicates that a positive correlation exists between the morphologically complete expression of endogenous virus genes in L2C leukemic cells and malignancy, particularly leukemia, in guinea pigs. 79-1599 Biological Properties and Translational Products of Three Independent Isolates of Feline Sarcoma Virus. (Eng) Porzig, K. J. (Lab. Cellular and Molecular Biology, NCI, Bethesda, MD, 20014); Barbacid, M.; Aaronson, S. A. *Virology* 92(1): 91-107; 1979.

The biological properties and translational products of three transforming strains of feline sarcoma virus (FeSV), SM, GA, and ST, were characterized. The three retroviruses were isolated independently from naturally occurring tumors of outbred cats. Like previous mammalian transforming viruses, each FeSV strain was demonstrated to be replication-defective, requiring a C-type RNA virus as a helper. Reproducible differences were demonstrated in the morphology of transformed foci induced by each FeSV strain. These findings were independent of helper virus or assay cell utilized, suggesting that the transforming activities of the three FeSV strains are distinguishable. Nonproducer transformants of SM-FeSV expressed the feline leukemia virus (FeLV) *gag* gene products p15, p12, and p30. In contrast, the GA- and ST-FeSV genomes coded only for p15 and p12 proteins, further distinguishing SM-FeSV from the other FeSV strains. Each remained stable with respect to viral protein expression upon transmission to new cells, demonstrating the stable association of FeLV *gag* gene information with each FeSV genome.

Analysis of the FeLV structural proteins translated in non-producer transformants of the three FeSV strains revealed the presence of precursor molecules whose sizes could not be accounted for solely by the number of FeLV *gag* proteins present in them. (43 refs)

79-1600 Antibody Response in Cats to Feline Leukemia Virus Reverse Transcriptase under Natural Conditions of Exposure to the Virus. (Eng) Jacquemin, P. C. (Lab. Tumor Cell Biology, NCI, NIH, Bethesda, MD, 20014); Saxinger, C.; Gallo, R. C.; Hardy, W. D.; Essex, M. *Virology* 91(2): 472-476; 1978.

The sera of feline leukemia virus (FeLV)-exposed, feline sarcoma virus (FeSV)-exposed, and unexposed cats were examined for the presence of natural antibodies to reverse transcriptase (RT). The 68 animals studied belonged to one of five groups: (A) specific pathogen-free cats known to be unexposed to FeLV and FeSV; (B) randomly collected healthy street cats; (C) household cats known to have been exposed to FeLV under natural conditions; (D) cats with pathologically confirmed cases of lymphoma or lymphoid leukemia acquired under natural conditions; and (E) specific pathogen-free cats injected with their own cells that had been infected in the laboratory with FeLV or FeSV. Antibodies to RT were detected only in nonviremic cats. All sera with anti-RT activity also contained antibody to feline oncornavirus membrane-associated antigen (FOCMA), but sera from 2 Group B cats, 5 Group C cats, and 1 Group E cat contained moderate or high levels of anti-FOCMA without neutralizing activity for FeLV RT. The results of an assay for neutralization of RT functional activity suggested that RT antibody activities were sometimes discordant from those directed to FOCMA. (33 refs)

79-1601 Feline Leukemia Virus: Survival Under Home and Laboratory Conditions. (Eng) Francis, D. P. (Dept. Microbiology, Harvard Sch. Public Health, Boston, MA, 02115); Essex, M.; Gayzagian, D. *J Clin Microbiol* 9(1): 154-156; 1979.

The stability of feline leukemia virus (FeLV) released into the environment was studied. The studies included salivary FeLV survival on a dry surface similar to surfaces found in homes and FeLV survival in laboratory culture medium to simulate conditions in research laboratories. Titers of infectious salivary FeLV dropped rapidly in saliva that was allowed to dry on glass cover slips at room temperature. Loss of infectious virus was also observed when FeLV from a non-saliva source was allowed to dry. Levels of infectious FeLV in media dropped to < 10 infectious units within 60 min after drying. Cell-free FeLV in cell culture medium was stable at temperatures from 4 to 37 C, but there was a rapid (within 3-4 hr) loss of infectiousness at 56 C. Although the infectiousness of salivary FeLV declined relatively rapidly on dry surfaces, the 30- to 60-min interval during which significant FeLV could still be detected might be adequate to transfer

the agent. The relative stability of FeLV suggests that transmission could also occur through the sharing of common food and water containers. Owners of infected pet cats might also be exposed to high levels of FeLV depending on their interactions with their cats, and the potential for human infection in the laboratory seems considerable. 79-1602 Activation of Feline Complement by Feline Leukemia Virus (Meeting Abstract). (Eng) Kobinsky, L. (Sloan-Kettering Inst. for Cancer Res., New York, NY, 10021); Hardy, W. D.; Ellis, R.; Day, N. K. *Fed Proc* 38(3, part 2): 1010; 1979. (no refs)

79-1603 Induction of C-Type Virus in Cell Lines Derived from Calf Form Bovine Lymphosarcoma. (Eng) Onuma, M. (Dept. Epizootiology, Faculty Veterinary Medicine, Hokkaido Univ., Sapporo 060, Japan); Okada, K.; Yamazaki, Y.; Fujinaga, K.; Fujimoto, Y.; Mikami, T. *Microbiol Immunol* 22(11): 683-691; 1978.

Serologic tests, electron microscopy, and a reverse transcriptase assay were used to study the induction of C-type virus by 5'-iodo-2-deoxyuridine (IUdR) and glucocorticoid dexamethasone (DXM) in cell cultures derived from adult form (ALS), calf form (CLS), and thymic form (TLS) bovine lymphosarcoma. Bovine leukemia virus (BLV) antigen was consistently detected in untreated ALS 3153 and 3169 cultures but not in any of the other untreated cultures. BLV particles were also detected in untreated ALS 3169, and a few were detected in CLS 3182, but none were found in any of the other untreated cultures. After treatment with IUdR or DXM, BLV antigen and BLV particles were detectable in CLS 3178 cells which changed from a epithelioidlike to a fibroblastlike morphology and began proliferating rapidly. The reverse transcriptase assay was positive for ALS 3153 and CLS 3178. The other cultures remained negative for virus antigen, particles, and reverse transcriptase after chemical treatment. (Eng) Shah, K. (Johns Hopkins Univ., Baltimore, MD); Jenson, A. B.; Pass, F.; Lancaster, W. D.; Olson, C. *Fed Proc* 38(3, part 2): 1070; 1979. (no refs)

79-1607 Cholesterol Content and Metabolism in Normal and Polyoma Virus-transformed Hamster Embryo Fibroblasts. (Eng) Mark-Malchoff, D. (Dept. Biochemistry, Univ. Rochester Sch. Medicine and Dentistry, Rochester, NY, 14642); Marinetti, G. V.; Hare, J. D.; Meisler, A. *Exp Cell Res* 118(2): 377-381; 1979.

Free and esterified cholesterol (CE) levels were determined by thin-layer chromatography in normal hamster embryo fibroblasts (HEF) and their polyoma virus-transformed counterparts (HFT). The total CE level was 6.8 and 6.6 $\mu\text{g}/10^6$ cells in HEF and HFT cells, respectively. However, the free CE level was 6.6 $\mu\text{g}/10^6$ HEF cells and 4.2 $\mu\text{g}/10^6$ HFT cells, but that of esterified CE was 0.2 $\mu\text{g}/10^6$ HEF cells and 2.4 $\mu\text{g}/10^6$ HFT cells. Thus, the free CE:CE ester ratio was 41.5 in normal cells and 1.8 in the transformed cells. CE uptake was 995 picomoles (pmol)/ 10^6 HEF cells/hr compared with 625 pmol/ 10^6 HFT cells/hr. The normal cells also took up more CE oleate than their transformed counterparts. However, the esterification of CE was higher and the hydrolysis of CE oleate was lower in HFT cells. This partly explains the difference in the free CE:CE ratio between the normal and transformed cells. The significance of the altered lipid composition of HFT cells may be related to the enhanced uptake of nutrients by these cells, possibly conferring on them an advantage for growth. (39 refs)

79-1608 Studies on Polyoma Virus DNA Replication in Synchronized C3H2K Cells. (Eng) Loche, M. P. (Fondation Curie-Institut du Radium, 15, rue Georges Clemenceau, Batiment 110, 91405 Orsay, France). *J Gen Virol* 42(2): 429-433; 1979.

The temporal relationship between polyoma virus DNA synthesis (VDS) and cellular DNA synthesis (CDS) was studied in C3H2K mouse kidney fibroblasts arrested in G_1 and infected at different times after serum stimulation (SS) to progress to the S phase. CDS was measured by ^3H -thymidine pulse-labeling and cell counts. VDS was determined by DNA infectivity titrations using plaque-purified virus and by isolating virus DNA form I on equilibrium density gradients. Both methods gave almost identical results with respect to the kinetics of VDS. VDS was max in the middle of the S phase, and VDS and CDS proceeded almost synchronously. VDS was only slightly delayed in cells infected up to 12 hr after SS, compared with cells infected immediately after SS. However, when cells were infected > 13 hr after SS, when they had already entered the S phase, VDS was delayed until the next S phase. Apparently, the early virus information needed to initiate viral DNA replication must be expressed before a critical period of the S phase is attained. The similar yields and kinetics of VDS recorded in cells infected before and 12 hr after SS indicate that SS factors can efficiently replace the

early virus host DNA stimulation function. When cells were incubated in serum that had lost its capacity to stimulate host DNA synthesis by preabsorption with growing cells, normal yields of polyoma DNA were still obtained, which shows that extensive replication of host DNA is not obligatory for virus DNA replication. 79-1609 RNA Hybridization to DNA Coupled with Cyanogen-Bromide-activated Sephadex: The Purification of Polyoma Messenger RNA. (Eng) Siddell, S. G. (Institut für Virologie und Immunbiologie, Justus-Maximilians-Universität Würzburg, Versbacher Landstrasse 7, D-8700 Würzburg, W. Germany). *Eur J Biochem* 92(2): 621-629; 1978.

A method for purifying RNA by hybridization to complementary DNA immobilized on cyanogen bromide-activated Sephadex is described and is illustrated by the purification of polyoma messenger RNA. It is necessary to elute RNA from DNA-Sephadex by a combination of formamide buffers containing NaCl and by elevated temperatures, conditions that dissociate DNA-RNA hybrids and also prevent the binding of RNA to the resin by ion exchange. 79-1617 The Growth Stimulation of SV3T3 Cells by Transferrin and Its Dependence on Biotin. (Eng) Young, D. V. (Dept. Chemistry, Boston Univ., Boston, MA, 02215); Cox, F. W.; Chipman, S.; Hartman, S. C. *Exp Cell Res* 118(2): 410-414; 1979.

Studies were conducted to identify factors critical for the growth stimulation of SV3T3 cells, a virally transformed derivative of the mouse fibroblast cell line 3T3. Iron in the ferrous form or in the ferric state with a suitable complexing agent was identified as a critical nutrient for SV3T3 growth. Both Hb and transferrin were capable of stimulating SV3T3 proliferation in low-serum or serum-free biotin-supplemented medium. SV3T3 cells did not grow in serum-free medium without iron. Growth is restored, although not to the levels obtained with saturating calf serum, upon the radiation of ferrous sulfate, Hb, or transferrin. Biotin addition alone did not stimulate SV3T3 growth, but its presence was required for growth stimulation by ferrous sulfate, transferrin, or Hb. The reason for this dependence on biotin is not known. The results also indicate that in addition to biotin and transferrin, unidentified serum growth factors are still needed to maximize the initial growth rate of SV3T3 cells. (12 refs)

79-1618 Factors Affecting the Frequency of Transformation of Rat Embryo Cells by Simian Virus 40. (Eng) Risser, R. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Pollack, R. *Virology* 92(1): 82-90; 1979.

An earlier observation that simian virus 40 (SV40) induces distinct patterns of transformed behavior upon infection of primary rat cells was confirmed, and factors influencing their generation were explored. The transformation of primary Fischer rat embryo cells into established cell lines by SV40 was monitored by the different restrictive assays of colony formation in sparse culture, dense colony or focus formation on a confluent cell sheet, and colony formation in semisolid medium. The primary embryonic rat cell cultures were con-

siderably less susceptible to infection and subsequent transformation than the established mouse 3T3 cell line or later in vitro passages of rat cells. These embryonic cells showed a stage-specific susceptibility to transformation but not to infection, with max susceptibility being achieved on gestation days 15-16. All transformed cell lines derived from SV40 infection of primary rat cells expressed viral tumor (T) antigen, as detected by immunofluorescence, although they differed greatly in their plating efficiency in semisolid medium containing methylcellulose. Only the assay of colony formation in semisolid medium selected directly for transformants that plated well in that medium, but all assays appeared to select for cell lines containing viral T antigen. (32 refs)

- 79-1619 Deletion Mutants of Simian Virus 40 Defective in Biosynthesis of Late Viral mRNA.** (Eng) Lai, C. J. (Lab. Molecular Virology, NCI, NIH, Bethesda, MD, 20014); Khoury, G. *Proc Natl Acad Sci USA* 76(1): 71-75; 1979.

Simian virus 40 deletion mutants lacking sequences in the late genomic region were examined for genetic elements that control the biosynthesis of the viral messenger RNA's (mRNA's). Mutant-specific RNA from infected cells was identified by CH₃Hg(OH)/agarose gel electrophoresis and mapped by the nuclease S1 technique. Altered 16S or 16S + 19S RNA species, shortened by a size equivalent to the deletion region, could be detected in cells infected with mutants lacking sequences within the body RNA segments. On the other hand, mutants that lacked the 5' end of the body sequences (a splice junction) failed to accumulate the respective shortened RNA species. In particular, mutant dl-2301, whose deletion includes both the leader and body splice junctions plus the intervening sequences, exhibited a polar effect on a distal gene. Although the late region of dl-2301 could be transcribed normally, the mutant defect appeared to be associated with little or no accumulation of the mutant-specific late RNA in the infected cells. These results suggest that splice junctions and/or the intervening sequences in the viral genome are control signals for posttranscriptional processing of the viral RNA. (24 refs)

- 79-1620 Enhancement of Simian Virus 40 Uptake by Permissive, Semi-permissive and Non-permissive Cells.** (Eng) Tan, K. B. (Wistar Inst. Anatomy and Biology, 36th and Spruce Sts., Philadelphia, PA, 19104). *Cytobios* 20(79/80): 143-149; 1977.

Various reagents were tested for their ability to enhance simian virus 40 (SV40) uptake in permissive (monkey), semipermissive (human), and nonpermissive (mouse, chick, snake, and fish) cells. Arginine-rich histones and diethylaminoethanol (DEAE)-dextran markedly enhanced virus uptake in all three types of cells. Optimum enhancement of virus uptake occurred at a DEAE-dextran concentration of 100 µg/ml. Under the conditions tested, DEAE-dextran was not cytotoxic but the histones were. Nuclear uptake of virus was

rapid, with a 50% uptake occurring within 12-14 min for human and mouse cells and 20 min for monkey cells. The increased cellular uptake of virus may result from the uptake of virus aggregates formed in the presence of DEAE-dextran. (12 refs)

- 79-1621 Variant Lines of Mouse Kidney Cells Transformed by an SV40_{tsA} Mutant with Growth Properties of Wild-Type Transformed Cells at Nonpermissive Temperature.** (Eng) Otsuka, H. (Div. Biochemical Virology, Baylor Coll. Medicine, Houston, TX, 77030); Dubbs, D. R.; Kit, S. *J Gen Virol* 42(2): 373-386; 1979.

A BALB/c mouse kidney line (mKSA207) transformed by a *tsA* mutant of simian virus 40 (SV40) is temperature-dependent for expression of the "standard transformed phenotype." At the permissive temperature (33.5 C), the mKSA207 cells resembled wild-type (wt) SV40 transformants: they contained intranuclear SV40 tumor (T) antigen, grew to high saturation density in monolayer culture in either 10% or 0.5% serum and also in methylcellulose suspension culture (MCSC); and became multinucleate in cytochalasin B. At the nonpermissive temperature (39.8 C), the mKSA207 cells lost some of their transformed properties: they grew only to low density in 10% serum, hardly grew at all in 0.5% serum or in MCSC, and remained mono- or binucleate in cytochalasin B. At 40 C in low serum, mKSA207 cells lost the intranuclear T antigen, and when they were fed 10% serum at 39.8 C, they accumulated large amounts of T antigen in the cytoplasm. Derivatives of mKSA207 were selected at 39.8 C in liquid medium and in MCSC. The heat-adapted lines, like wt SV40 transformants, exhibited the standard transformed phenotype at both 33.5 and 39.8 C. It is unlikely that acquisition of temperature-independence for the transformed phenotype was due to reversion of the *tsA* gene to wild-type, because the heat-adapted cell lines displayed the cytoplasmic T antigen at 39.8 C, and SV40 rescued from one of the heat-adapted lines was temperature-sensitive for growth. The T-antigen levels (complement fixation units/10⁶ cells) of heat-adapted lines grown at 39.8 C were comparable to those of mKSA207 cells grown at 33.5 or 39.8 C. (37 refs)

- 79-1622 Establishment and Characterization of Indian Muntjak Cell Lines Transformed with Simian Virus 40.** (Eng) Yamaguchi, N. (Inst. Medical Science, Univ. Tokyo, 4-6-1 Shirokanedai, Minato-ku, Tokyo 108, Japan); Huh, N. *J Gen Virol* 42(2): 289-296; 1979.

The kidney cells of an Indian muntjak (*Muntiacus muntjak vaginalis*) were transformed with simian virus 40 (SV40). The transformation efficiency of the tertiary cultures was very high when estimated by the agar suspension culture method, being about 0.015% at an input multiplicity of 0.4 plaque-forming unit/cell. Clonal cell lines were established from the colonies in soft agar and characterized. SV40 tumor antigen was detected in the nuclei of nearly all the cells of any clone. Infectious SV40 was detected in all but one clone.

The yield of infectious SV40 was enhanced 30-fold and the percentage of virion antigen-positive cells in a clone was increased from 0.2% to 40% by treatment with mitomycin C. More than 70% of the cells in two cell lines had normal G- and C-banded karyotypes, indicating that chromosomal change is not a necessary step in the transformation of Indian muntjak cells with SV40. (30 refs)

79-1623 Evolutionary Variants of Simian Virus 40: Cellular DNA Sequences and Sequences at Recombinant Joints of Substituted Variants. (Eng) Gutai, M. W. (Dept. Viral Oncology, Roswell Park Memorial Inst., Buffalo, NY); Nathans, D. *J Mol Biol* 126(2): 275-288; 1978.

Cellular DNA and host-viral joints present in the recombinant genome of an evolutionary variant of simian virus 40 (SV40) were analyzed at the nucleotide sequence level. Cellular DNA segments were interspersed with viral DNA and were arranged in part as tandem sequence repetitions. Some of the cellular DNA was derived from highly repeated sequences of host cell DNA, and it corresponded to sequences found in other substituted SV40 variants. Ten recombinant host-viral joints were identified in the variant genome, six of which showed distinct nucleotide sequences on both sides of the joint. In all but one case, sequences about the joint were rich in clusters of A-T base pairs. In one case, joint sequences could be compared with both viral and cellular sequences from which they were derived: short interrupted stretches of homology with each parental sequence were detected. Of the five remaining joints, which could be compared only with the SV40 parental sequence, two showed patchy homology with SV40 sequences adjacent to the joint. It is concluded that recombination between SV40 and cellular DNA occurs at many different nucleotide sequence positions in both parental DNA's, that extensive nucleotide sequence homology is not required for such recombination, that discontinuous or patchy homology may play a role in this event, and that A-T clusters may increase the probability of recombination at a given site. (26 refs)

79-1624 Evolutionary Variants of Simian Virus 40: Nucleotide Sequence of a Conserved SV40 DNA Segment Containing the Origin of Viral DNA Replication as an Inverted Repetition. (Eng) Gutai, M. W. (Dept. Viral Oncology, Roswell Park Memorial Inst., Buffalo, NY); Nathans, D. *J Mol Biol* 126(2): 259-274; 1978.

The predominant evolutionary variant of simian virus 40 (SV40) was cloned from the 45th passage stock (BSC-1 cells) and its genome was analyzed by electron microscopy, restriction endonuclease cleavage, and nucleotide sequence determination. The variant genome consisted of SV40 DNA joined to cellular DNA, and it was made up of three tandemly arranged repeats of a basic DNA segment that was 28% of the length of wild-type SV40 DNA. Within each basic segment, the SV40 sequences derived from the region of the replication origin were present as an inverted repetition. There were 164

nucleotides of SV40 DNA on one side of the inverted sequence and 198 nucleotides on the other side. The variant sequence was the same as that found in parental SV40 DNA except for the presence of small tandem repeats within the variant segment. These data, combined with the results of other studies of SV40 variants and deletion mutants, localize the SV40 origin signal to a segment of DNA of about 80 nucleotides between map units 0.66 and 0.68. (44 refs)

79-1625 Heterogeneity and 5'-Terminal Structures of the Late RNAs of Simian Virus 40. (Eng) Ghosh, P. K. (Dept. Internal Medicine and Human Genetics, Yale Medical Sch., New Haven, CT, 06510); Reddy, V. B.; Swinscoe, J.; Lebowitz, P.; Weissman, S. M. *J Mol Biol* 126(4): 813-946; 1978.

The 5'-terminal structures of the late lytic RNA's of simian virus 40 (SV40) were studied by binding the plus strand of small DNA fragments labeled in the 5'-terminal position with ³²P to specific regions of cytoplasmic polyadenylated late RNA, extending these "primer" fragments in a 3' direction with reverse transcriptase, fractionating the extended products on denaturing polyacrylamide gels, and performing DNA sequence analyses on the extended products. Four categories of extension products, indicative of four different classes of late 19S RNA, were detected. One class was colinear with SV40 DNA at its 5' terminus, while three classes contained splices that fused residue 476 at the 5'-terminus of the body of this RNA to residues 444, 291, and 212, respectively. The most abundant 19S species contained the splice from residues 291-476. The extension products terminated at a number of different sites. Multiple species stopped at residues 182 and 243 with the sequence T-A-A. These sites probably represent the 5'-termini of in vivo species of 19S RNA's, and the available evidence suggests that extended products stopping at other sites with the sequences T-A(A) and T-A, as well as certain other sequences, may also arise from discrete in vivo RNA's. For each of the three different gaps found in the late 19S RNA's, as well as for four additional gaps analyzed in the late 16S and early 19S RNA's of SV40, identical di-, tri-, or tetranucleotide sequences lay on the un-gapped precursor at sites that underwent splicing. These sequences may be involved in determining the specificity of the splicing reaction. (80 refs)

79-1626 Interference in SV40 DNA Infections: A Possible Basis for Cellular Competence. (Eng) Wilson, J. H. (Marrs McLean Dept. Biochemistry, Baylor Coll. Medicine, Houston, TX, 77030). *Virology* 91(2): 380-388; 1978.

The ability of other DNAs to interfere with infection by wild-type simian virus 40 (SV40) DNA was studied. Temperature sensitive (ts) SV40 DNA interfered with plaque formation by nondefective tester DNA in the first cycle of infection. Apparently, the interference phenomenon primarily limited the number of cells in which a normal infection was initiated.

Linear ts SV40 DNA's interfered about 5- to 10-fold less efficiently than the corresponding closed-circular DNA's, and structurally similar closed-circular DNA's (SV40, PM2 and X174) varied over a 100-fold range in their ability to interfere. The difference in interference by structurally similar DNA's suggests that interference may be influenced by nucleotide sequence. Plaque formation by tester DNA was interfered with when its infection was preceded by infection with interfering DNA, but when infection by tester DNA preceded infection by interfering DNA, interference was not observed. The results suggest that: interference occurs early in infection and is independent of any viral gene product; interference occurs after the DNA's interact with the cell; interference depends in part on nucleotide sequence information, suggesting that the site of interference may be intracellular, perhaps nuclear; and interference could be the basis for the limited response of African green monkey kidney cells to SV40 DNA that has previously been attributed to cellular "competence." - 79-1627 SV40-transformed Human Diploid Cells That Remain Transformed Throughout Their Limited Lifespan.** (Eng) Gotoh, S. (Dept. Microbiology and Immunology, Div. Biology and Biomedical Sciences, Washington Univ. Sch. Medicine, St. Louis, MO, 63110); Gelb, L.; Schlessinger, D. *J Gen Virol* 42(2): 409-414; 1979.

WI-38 human diploid fibroblasts (FB's) were infected with simian virus 40 (SV40), apparently transformed foci were identified and subcultured, and the foci were observed as they approached crisis to determine why SV40 infection of FB cultures induces the survival of rare cells that can grow into permanent cell lines. Three to 6 wk after infection, 91 well-separated foci were identified; however, only 46 grew sufficiently to be expanded to a confluent culture in a 60-mm petri dish. The fastest-growing (earliest-appearing) foci were subcultured most successfully. None of the foci were able to grow in soft agar. Twenty-four foci grew only through passage 41; the remaining 22 foci survived to a max of 64-65 passages. During the entire growth period, including crisis, the cells of each subculture showed the morphology and SV40 tumor-antigen positivity of transformed cells, which indicates that SV40 transformation per se is insufficient to confer indefinite growth on human diploid FB's. These results are consistent with the commitment theory of FB senescence, which suggests that FB tend to lose their capacity for indefinite growth by an irreversible change (commitment) that occurs many generations before cell division ceases. However, this theory does not explain how SV40 transformation promotes the survival of any cells from mass culture. Either uncommitted cells can exist in cultures in crisis but cannot overgrow the mass of undividing cells or SV40 transformation can reverse the terminal cessation of cell division in rare cells. If reversal of commitment is required to promote survival, a special transformation event must also be postulated or survivors would be more common. The only hint of a possible physiological correlate of this event noted was the inability of the 91 subcultures to grow in soft agar. (21 refs)

- 79-1628 Karyotype Evolution of the Simian Virus 40-transformed Human Cell Line LNSV.** (Eng) Begovich, A. (Dept. Pediatrics, Univ. California, San Diego Sch. Medicine, La Jolla, CA); Francke, U. *Cytogenet Cell Genet* 23(1/2): 3-11; 1979.

Trypsin-Wright's banding was used to analyze the chromosomes of two sublines of the simian virus 40-transformed Lesch-Nyhan cell line LNSV, which was derived from the fibroblasts of a patient with hypoxanthine-guanine phosphoribosyltransferase (HGPRT) deficiency. The chromosome number per cell in the subline GM-847 ranged from 64 to 90 with a mean of 77; that in subline LNSV ranged from 62 to 81 with a mean of 75. Some chromosomes were present at about the same frequency in both sublines, whereas others, especially 2, 7, 11, and 18, were much more common in GM-847. Nineteen rearranged chromosomes that were observed in at least 40% of metaphases were set aside as marker chromosomes, and their probable derivation from normal chromosomes was described according to Paris Conference (1971) nomenclature. Most markers were the result of apparent terminal deletions, although some resulted from translocations, interstitial deletions, or duplications. In addition to these markers, each cell possessed a number of unique rearrangements. Heterogeneity within the two sublines appeared to increase with time in culture, and no evidence was found for evolution of a karyotypically stable cell population. (23 refs)

- 79-1629 Photodynamic Induction of an Oncogenic Virus In Vitro.** (Eng) Bockstahler, L. E. (Health, Food and Drug Admin., Rockville, MD, 20857); Cantwell, J. M. *Biophys J* 25(1): 209-213; 1979.

A study was carried out with simian virus 40 (SV40)-transformed hamster kidney cells to determine whether photodynamic induction of virus can occur with a mammalian virus-host system. Cell cultures were treated with different concentrations of proflavine (0-12 μ M), exposed to visible light for 1 hr (10^3 J/m²), and incubated for virus expression. For the range of dye concentrations examined, induction of SV40 was observed between 0.5 and 3 μ M. The optimum level of SV40 induced (1 μ M proflavine) represented an increase in virus production of three orders of magnitude above the spontaneous background level. No virus induction above background levels was found by treatment of cells with either proflavine or light alone. These results demonstrate that photodynamic induction of virus can occur with a mammalian virus-host cell system. (11 refs)

- 79-1630 Binding and Transcription of Native and Chemically Modified SV40 DNA by *Escherichia coli* DNA-dependent RNA Polymerase.** (Eng) Hale, P. L. (Birmingham Medical Center, Univ. Alabama, Birmingham, AL). *Diss Abstr Int B* 39(8): 3697; 1979. (no refs)

- 79-1631 Structural Relationship Between the 100,000- and 17,000-Molecular-Weight T Antigens of Simian Virus 40 (SV40) as Deduced by Comparison with the SV40-specific Proteins Coded by the Nondefective Adenovirus Type 2-SV40 Hybrid Viruses.** (Eng) Linke, H. K. (Molecular Biology Inst., Univ. California, Los Angeles, CA, 90024); Hunter, T.; Walter, G. *J Virol* 29(1): 390-394; 1979.

The two-dimensional peptide maps of the methionine-containing tryptic peptides of the 100,000-dalton (100K) and 17K tumor (T) antigens of simian virus 40 (SV40) were compared. The 100K and 17K T antigens shared a common N-terminal region coded between the initiator AUG triplet at 0.65 map units and 0.59 map units, whereas none of the sequences in the 17K antigens arose from the region between 0.54 and 0.17 map units. The 17K T antigen had 2 peptides not found in the 100K T antigen and the 100K T antigen had 14 unique peptides. The unique sequences of the 17K T antigen probably originate between 0.59 and 0.54 map units. An almost complete identity existed between the peptides of 100K T antigen and those of the 95K protein of cells infected by a nondefective adenovirus type 2-SV40 hybrid virus. This, coupled with the demonstrated absence of peptides R and S in the 95K protein, suggests that the messenger RNA (mRNA) for the 95K protein is lacking the sequences between 0.59 and 0.54 map units and has undergone the same splicing event as the smaller of the two early SV40 mRNA's, which codes for the 100K T antigen. These data support a proposed model for the expression of the early region of SV40. (22 refs)

- 79-1632 Serological Evidence for Antigenic Differences Between the Mason-Pfizer Monkey Virus (MPMV) and an MPMV-like Virus (PMFV) Detected in a Malignant Permanent Human Cell Line.** (Eng) Micheel, B. (Central Inst. Cancer Res., Academy Sciences of the GDR, Lindenberger-Weg 70/80, DDR-1115 Berlin-Buch, E. Germany); Baumbach, L.; Wunderlich, V.; Niezabitowski, A.; Bierwolf, D. *Eur J Cancer* 15(1): 101-108; 1979.

Mason-Pfizer monkey virus (MPMV) and an MPMV-like virus (PMFV) detected in a malignant continuous human cell line were compared in immunofluorescence tests. Anti-MPMV and anti-PMFV sera reacted specifically with the cytoplasm of both MPMV- and PMFV-infected but not with uninfected cells. Immunofluorescence absorption showed that, in addition to the common specificities, both viruses have distinct antigens. It was not possible, under the conditions of this experiment, to determine on which polypeptide these antigenic determinants are localized. It is concluded that MPMV and PMFV must be regarded as different types of a closely related virus group. (23 refs)

- 79-1633 Sarcoma Virus-specific Phosphoproteins are Packaged in "Rescued" Type C Virions.** (Eng) Sen, A. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Halverson, D. O.; Rapp, U. R.; Todaro, G. J.

Virology 92(1): 245-251; 1979.

Phosphorylated proteins in sarcoma virus pseudotypes obtained by acute infection of nonproductively transformed cell lines with a variety of helper viruses were analyzed by denaturing gel filtration. Each sarcoma virus appeared to specify at least one major structural phosphoprotein that was present in the pseudotype virions but not in the helper virions. The major phosphoprotein specific for particular sarcoma virus pseudotypes appeared to be independent of the cell lines. However, the amount of the new phosphoprotein relative to the helper structural phosphoprotein varied with the helper used as well as with the time elapsed between the establishment of an acute infection with helper virus and the analysis of phosphoprotein in the pseudotypes. Nuclease treatment did not alter the av mol wt or the size heterogeneity of the sarcoma virus-specific phosphoprotein molecules, which suggested that they are not covalently conjugated nucleoprotein complexes. These sarcoma viral phosphoproteins or related products may be involved in the maintenance of transformation in culture and/or tumor immunity in virus-exposed animals. (29 refs)

- 79-1634 Studies of Simian Sarcoma and Simian Sarcoma-associated Virus: I. Analysis of Viral Structural Proteins, and Preparation and Characterization of Antiserum Specific for Viral Envelope Components.** (Eng) Deinhardt, F. (Pettenkofer Institut, Pettenkoferstrasse 9a, D-8000 Munich 2, W. Germany); Bergholz, C.; Hunsmann, G.; Schneider, J.; Thiel, H. J.; Beug, H.; Schafer, W. *Z Naturforsch C* 33(11/12): 969-980; 1978.

The structural proteins of simian sarcoma virus (SSV) and simian sarcoma-associated virus (SSAV) were analyzed by gel electrophoresis, and a virus-specific antiserum that appears to react predominantly with viral envelope components was prepared and characterized. The protein pattern of SSV was very similar to that of murine leukemia virus (MuLV). The major polypeptides identified were glycoproteins of 69,000 and 71,000 daltons (gp69/71), envelope proteins p15(E) and p12(E), and internal proteins p31, p15, p12, and p10. As in MuLV, p12 stained reddish with Coomassie blue, but a p15 core protein [p15(C)] analogous to the p15(C) of MuLV and distinct from p15(E) was not clearly identified. Using antisera specific for individual components of Friend leukemia virus (FLV), cross-reactions were observed between proteins p15(E), p12(E), and p31 of SSV and FLV and, to a minor degree, between their respective major glycoproteins. An antiserum reacting strongly, specifically, and almost exclusively with SSV gp69/71, p15(E) and p12(E) was prepared by inoculating a goat with its own cells that had been transformed in vitro with SSV and grown in goat serum. Comparative studies with this antiserum in complement-fixation and Ouchterlony tests confirmed the reported strong antigenic similarities between SSV and gibbon ape lymphoma virus but did not identify any interspecies reactivity. This lack of interspecies reactivity may impair the value of the goat an-

tiserum for identifying and evaluating new viral isolates or viral components from human material. (82 refs)

- 79-1635 Antibody Responses to Herpesvirus Papio Antigens in Baboons with Lymphoma.** (Eng) Neubauer, R. H. (Biological Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Rabin, H.; Strnad, B. C.; Lapin, B. A.; Yakovleva, L. A.; Indzie, E. *Int J Cancer* 23(2): 186-192; 1979.

An Epstein-Barr virus-related herpesvirus, termed herpesvirus papio (HVP), was isolated from baboons (*Papio hamadryas*) at the Institute of Experimental Pathology and Therapy, Sukhumi, USSR, where there is a continuing outbreak of lymphoma. Sera from diseased baboons and from age- and sex-matched control animals were examined for antibodies to HVP antigens. Animals with lymphoid disease had antibodies to HVP virus capsid, early, soluble, and nuclear antigens at higher frequencies and at higher titers than did control animals. Antibody titers were not age- or sex-related. No concordancy was detected for antibodies to soluble and nuclear antigens. Examination of the sera for antibodies to two other widely distributed viruses of hamadryas baboons, cytomegalovirus and foamy virus, did not indicate a disease-related role for either of these viruses. (29 refs)

- 79-1636 Expression of Fc Receptors, Ia Antigens, and B2 Microglobulin after In Vitro Herpes Simplex Virus Infection of Human Lymphoid Cells (Meeting Abstract).** (Eng) Dorval, G. (Royal Victoria Hosp., Montreal, Canada H3A 1A1); Bourkas, A. F.; Menezes, J. *Fed Proc* 38(3, part 2): 927; 1979. (no refs)

- 79-1637 Polyamine Turnover and Leakage During Infection of HeLa and L-Cells with Herpes Simplex Virus Type 1.** (Eng) McCormick, F. (Translation Lab., Imperial Cancer Res. Fund, London WC2, England). *Virology* 91(2): 496-503; 1978.

Polyamine turnover was studied in HeLa and L cells during infection with herpes simplex virus type 1 (HSV-1). Little spermine was lost from uninfected L or HeLa cells; spermidine was lost more rapidly, presumably due to conversion to spermine. Infection of L cells with HSV-1 resulted in almost complete loss of spermidine and spermine within 20 hr, whereas HeLa cells lost only 18% and 26% of their spermidine and spermine, respectively, during infection. In uninfected HeLa and L cells, the specific activity of spermine decreased with a half-life of 22 and 25 hr, respectively. In infected cells, the specific activity of spermine remained constant, suggesting that spermine is not synthesized after infection. Changes in the specific activity of spermidine followed those of spermine. L cells became extremely permeable to polyamines early in infection, whereas HeLa cells did not. The addition of spermidine or spermine had little effect on the production of infectious virus, which was 20-fold greater in HeLa than in L cells. The data indicate that the cell

polyamine pools do not limit the production of infectious virus. (21 refs)

- 79-1638 Concanavalin A-mediated Agglutination of 3T3 Cells after Exposure to UV-irradiated Herpes Simplex Virus.** (Eng) Taguchi, F. (Dept. Microbiology, Kitasato Univ. Sch. Hygienic Sciences, Sagamihara-shi, Kanagawaken 228, Japan); Hara, K.; Nagaki, D. *Microbiol Immunol* 22(10): 597-608; 1978.

The effect of UV-irradiation of herpes simplex virus type 2 (HSV-2) on concanavalin A (Con A)-mediated agglutination (agg) of infected Swiss 3T3 cells was studied. HSV-2 was irradiated for 1-20 min before being injected into cultures at a multiplicity of infection of 2 plaque-forming units/cell. Virus was adsorbed for 90 min before the infected cells were examined for Con A agglutinability. Three different phases of agg were observed. The agglutinability began to increase at 3, 4, or 72 hr postinfection (pi). Early 1 agg, detected at 3 hr pi, was induced by treating cells with HSV-2 that was either active or irradiated <5 min, and it was inhibited by actinomycin D (1 µg/ml) or cycloheximide (50 µg/ml). Early 2 agg began to increase at 4 hr pi when cells were inoculated with HSV-2 irradiated for 7-20 min, and it was not affected by either inhibitor. HSV-2 irradiated for 6 min failed to induce either type of agglutinability. Late agg, observed 72 hr pi, was detected in cultures that had been treated with HSV-2 irradiated for 4-15 min. Virus irradiated for 6-8 min was most efficient at inducing late agg. HSV-2-transformed cells were agglutinated without exception by low concentrations of Con A. In addition, a high transformation rate was observed 3-4 wk pi in cell cultures exposed to HSV that had been irradiated for 6-8 min. These results indicate that the optimal duration of UV-irradiation of HSV-2 seems to be limited to 6-8 min for two different phenomena. (21 refs)

- 79-1639 Effect of Actinomycin D on the Expression of Herpes Simplex Virus-Common Surface Antigen in Cells Transformed by Herpes Simplex Virus Type 2.** (Eng) Kimura, S. (Dept. Bacteriology, Sch. Medicine, Tokushima Univ., Tokushima 770, Japan); Okazaki, K.; Yoshida, N.; Ohnishi, Y. *J Virol* 29(1): 161-169; 1979.

Using rabbit antiserum hyperimmune to herpes simplex virus type 1 (HSV-1), the expression of HSV common surface antigen(s) (CSA) was studied by indirect immunofluorescence using hamster cells transformed by HSV type 2 (155-4 cells) and derived tumor cells (155-4T). The effect of actinomycin D (A-D) treatment of the cells on CSA expression was also studied. Antiserum to HSV-1 reacted specifically with CSA on the plasma membranes of 155-4 and 155-4T cells. A peak of CSA-positive 155-4 cells was observed 3-5 hr after seeding, but no such peak was observed with 155-4T cells. The initial increase in CSA-positive 155-4 cells after seeding was maintained for 20 hr by treatment with A-D, the effect lasting for several hours after removal of the drug and being greatest with a drug concentration of 2 µg/ml. Treatment with A-D

did not affect CSA expression in 155-4T cells. The A-D effect of 155-4 cells was partially inhibited by 10-20 $\mu\text{g}/\text{ml}$ of puromycin and completely inhibited by 50 $\mu\text{g}/\text{ml}$, indicating that new protein synthesis was required for A-D-enhanced CSA expression. The protease inhibitor antipain (0.5 mM) did not affect growth or CSA expression of 155-4 cells, but it abrogated the enhancing effect of A-D. The data indicate that two kinds of CSA expression occur in transformed 155-4 cells: one type is expressed soon after seeding, does not require further protein synthesis, and is insensitive to antipain; the other is expressed in response to A-D, requires protein synthesis, and is sensitive to antipain. (32 refs)

79-1640 Herpes Simplex Virus Type 2 Functions Expressed During Stimulation of Human Cell DNA Synthesis. (Eng) Kucera, L. S. (Dept. Microbiology and Immunology, Bowman Gray Sch. Medicine, Wake Forest Univ., Winston-Salem, NC, 27103); Edwards, I. *J Virol* 29(1): 83-90; 1979.

To identify herpes simplex virus type 2 (HSV-2)-specific functions expressed during stimulation of human embryo fibroblast (HEF) DNA synthesis, cultures were partially arrested during DNA synthesis by pretreatment with 5-fluorouracil and maintained in 0.2% serum medium during virus infection. De novo RNA and protein syntheses were continuously required during HSV-2 stimulation of HEF DNA replication. During this stimulation, the virus markedly increased the rate of thymidine transport and intracellular thymidine metabolism. In addition, HSV-2-specific thymidine kinase (TK) activity was expressed. HSV-2 stimulation of HEF DNA synthesis represented predominantly semiconservative replication and some cell DNA repair. Thus, HSV-2 stimulation of cellular DNA synthesis involved at least four virus-specific functions: induction of thymidine transport, HSV-2 TK activity, semiconservative replication, and repair of cellular DNA. The ability of HSV-2 to stimulate human cell DNA synthesis suggests that the virus is capable of influencing the normal regulatory processes of resting cells. (21 refs)

79-1641 Characterization of Cross-reacting Antigens on the Epstein-Barr Virus Envelope and Plasma Membranes of Producer Cells. (Eng) Thorley-Lawson, D. A. (Sidney Farber Cancer Inst., Harvard Medical Sch., 44 Binney St., Boston, MA, 02115). *Cell* 16(1): 33-42; 1979.

A study was undertaken to design and implement a technique for characterizing and purifying the membrane antigen/neutralizing antigen complex of Epstein-Barr virus (EBV). A rabbit antiserum was prepared against the B95-8 transforming strain of EBV. The antiserum has a high virus-neutralizing titer (approx 1:1,000) against both marmoset B95-8 EBV and human P3HR-1 EBV. The neutralizing antibodies were absorbed completely with EBV producer cell lines, but not with nonproducer cell lines or producer cell lines treated with phosphonoacetic acid (PAA), which blocks expression of late

viral antigens. After repeated absorption with PAA-treated B95-8, the serum remained reactive with the membranes of producer cell lines, as determined by immunofluorescence or the ^{125}I -Staphylococcal protein A radioimmunoassay. Thus, neutralizing antigens are expressed on the membranes of producer cell lines. The polypeptides recognized by the antiserum were characterized by immunoprecipitation studies as having mol-wts of approx 150,000 and 75,000. Since the antiserum was raised against virions, these two polypeptides are probably virion structural proteins or their precursors, and at least one of them is probably part of the membrane antigen complex. (31 refs)

79-1642 Differences in EBV Receptor Concentration Between In Vitro EBV-converted Lymphoma Sublines Reflect Biological Differences Between the Converting Viral Substrains. (Eng) Klein, G. (Dept. Tumor Biology, Karolinska Institutet, S 104 01 Stockholm 60, Sweden); Manneborg, A.; Steinitz, M. *Int J Cancer* 23(2): 197-200; 1979.

The Epstein-Barr virus (EBV)-receptor concentration of two EBV-negative human B-cell lymphoma lines (BJAB and Ramos) was determined before and after in vitro conversion with the transforming B95-8 (B) or the cytopathic P3HR-1 (P) EBV substrains into permanent EBV-carrying sublines. Receptors were measured by a quantitative EBV-absorption bioassay. The absorption index of two B-virus-converted BJAB sublines was not significantly different from that of BJAB. In contrast, a P-virus-converted line showed significantly reduced EBV-absorbing capacity. The results were similar for Ramos and its converted sublines. Thus, the EBV-receptor concentration of all P-virus-converted sublines was significantly reduced compared with that of the B-virus-converted sublines. P-virus conversion of Ramos and BJAB has probably selected cells with a low but clearly positive EBV-receptor expression. Conceivably, cells with few receptors might be hit by a transforming particle without the major risk of also capturing a cytopathic particle, whereas cells with a high EBV-receptor concentration are more likely to capture both. (20 refs)

79-1643 Epstein-Barr Virus-Specific RNA. III. Mapping of DNA Encoding Viral RNA in Restraining Infection. (Eng) Powell, A. L. (Dept. Medicine, Univ. Chicago, Chicago, IL, 60637); King, W.; Kieff, E. *J Virol* 29(1): 261-274; 1979.

The location within the map of the Epstein-Barr virus (EBV) genome of the DNA that encodes the viral RNA in the polyadenylated [poly(A)+] and nonpolyadenylated [poly(A)-] RNA fractions of Namalwa cells (originally obtained from a Burkitt tumor) was studied. Hybridization of ^{32}P -labeled EBV DNA homologous to Namalwa poly(A)+ or poly(A)- RNA with restriction endonuclease fragments of EBV (B95-8) DNA indicated that these RNA's are encoded by DNA contained primarily in the *Hsu* I A/*Eco*RI A and

Hsu I B/*Eco*RI A fragments and, to a lesser extent, by DNA in other fragments of the EBV genome. Hybridizations of Namalwa poly(A)+ and poly(A)- RNA in soln to denatured labeled *Eco*RI A or B fragments, *Hsu* I A, B, or D fragments, and *Hsu* I A *Eco*RI A or *Bam* I S fragments and of Raji polyribosomal poly(A)+ RNA to the *Eco*RI A fragment indicated that Namalwa poly(A)+ RNA is encoded primarily by 6×10^5 daltons of a 2×10^6 -dalton segment of DNA, *Bam* I S, which is tandemly reiterated (approx 10 times) in the *Hsu* I A/*Eco*RI A fragment and is encoded to a lesser extent by DNA in the *Hsu* I B, *Eco*RI B, and *Hsu* I D fragments. Raji polyribosomal poly(A)+ RNA is encoded by a fraction of the *Eco*RI A fragment similar to the one that encodes Namalwa poly(A)+ RNA. The fraction of the *Bam* I S fragment homologous to Namalwa poly(A)- RNA is similar to the fraction homologous to Namalwa(A)+ RNA. However, Namalwa poly(A)- RNA is homologous to a larger fraction of the DNA in the *Hsu* I B, *Hsu* I D, and *Eco*RI B fragments. (56 refs)

79-1644 **Complementation of Infecting Epstein-Barr Virus by Intrinsic Viral Genomes in Human Lymphoblastoid Cells (Meeting Abstract).** (Eng) Lidin, B. (Dept. Microbiology, Univ. 79-1647 **Nonconditional Replication Mutants of Type C and Type D Retroviruses Defective in *gag* Gene-coded Polypeptide Post-translational Processing.** (Eng) Sacks, T. L. (Viral Genetics Section, Lab. Cellular and Molecular Biology, NCI, Bethesda, MD, 20014); Devare, S. G.; Blennerhassett, G. T.; Stephenson, J. R. *Virology* 91(2): 352-363; 1978.

The rapid isolation and preliminary characterization of nonconditional replication-defective mutants of C-type retroviruses of primate and nonprimate origin and a representative D-type retrovirus are described. By this means, 6 RD114, 3 M7 baboon, 4 Rauscher murine leukemia virus (R-MuLV), and 9 squirrel monkey retrovirus (SMRV) mutant clones were isolated. Although defective for virus production, all but

two of the mutant clones isolated were characterized by relatively high levels of *gag* and *env* gene-coded protein expression. Although expression of *gag* and *env* gene translational products was coordinate in most of the R-MuLV and SMRV mutant clones, certain clones nonproductively infected with either RD114 or M7 baboon virus showed noncoordinate synthesis. Further analysis of representative mutant clones indicated impaired *gag* gene-coded polypeptide posttranslational processing. This latter observation made possible identification of the component structural proteins of both RD114 and SMRV *gag* gene-coded precursor polypeptides. The susceptibility of many of the clones to superinfection by wild-type virus indicated that the defect in virus production was due to mutation in the viral, rather than host, genome. Several nonproductively infected clones, on the other hand, were resistant to superinfection. The demonstration of greater cross-interference to superinfection between M7, RD114, and SMRV than between any of these viruses and the amphotropic murine C-type virus isolate 4070-A corroborates the presence of shared envelope glycoprotein determinants between primate-derived C- and D-type viruses. (28 refs.)

79-1648 **Enhanced Induction of Growth of B Lymphoblasts from Fresh Human Blood by Primate Type-C Retroviruses (Gibbon Ape Leukemia Virus and Simian Sarcoma Virus).** (Eng) Markham, P. D. (Litton Bionetics, Inc., 7300 Pearl St., Bethesda, MD, 20014); Ruscetti, F.; Salahuddin, S. Z.; Gallagher, R. E.; Gallo, R. C. *Int J Cancer* 23(2): 148-156; 1979.

A systematic study was made of the infection of fresh human hematopoietic cells by primate C-type retroviruses. Continuously growing B-lymphoblast cell lines were established from the peripheral blood of 11/21 Epstein-Barr virus (EBV)-seropositive human donors after exposure to viruses of the gibbon ape leukemia virus (GALV)-simian sarcoma virus/simian sarcoma-associated virus (SiSV/SiSAV) group. The incidence of growth induction upon exposure to baboon endogenous virus (BaEV), feline leukemia virus (FeLV), or to uninfected monolayer cultures was < 10%. WBC from the peripheral blood of leukemic patients gave similar results, but exposure of fresh peripheral blood from eight normal EBV-seronegative donors to the same viruses did not result in induction of cell growth. The established cell lines were polyclonal B lymphoblasts, as determined by morphological, cytochemical, immunological, and functional properties. The cells expressed EBV nuclear antigen (EBNA test), formed rosettes with complement-activated sheep or bovine erythrocytes (EAC-rosette test), but not with untreated erythrocytes (E-rosette test), and were positive for one or more surface-bound immunoglobulins. They were also karyotypically normal, as determined by standard chromosome analysis and by trypsin-Giemsa banding techniques. However, unlike other reported newly established diploid B-lymphoblast cell lines, cells from approx 80% of the cultures tested grew as locally invasive tumors when inoculated into 1- to 3-wk-old athymic nude mice and formed colonies in semisol-

id medium. Lymphoblasts from nude mouse tumors were readily reestablished as suspension cultures that retained their lymphoblastic properties and remained karyotypically normal. These studies indicate that under certain conditions, C-type retroviruses of the GALV-SiSV/SiSAV group directly or indirectly increase the incidence of transformation of human B lymphocytes. 79-1649 Biology and Virology of the Human Malignant Lymphomas. 1st Milford D. Schulz Lecture. (Eng) Kaplan, H. S. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Goodenow, R. S.; Gartner, S.; Bieber, M. *Cancer* 43(1): 1-24; 1979.

Permanent cell lines were established from 12 diffuse histiocytic lymphomas (SU-DHL-1 to -12), 3 American Burkitt's lymphomas (SU-AmB-1 to -3), 2 acute lymphoblastic leukemias (SU-ALL-1 and -2), and 3 diffuse undifferentiated lymphomas (SU-DUL-1 to -3). The cultured cells displayed neoplastic characteristics, as manifested by heterotransplantability in congenitally athymic nude mice and by cytogenetic abnormalities in early passage generations. The three AmB and several of the DHL and DUL lines were of B-lymphocytic origin, whereas the two ALL lines were of T-lymphocytic origin. SU-DHL-1 and -2 appeared to be of true histiocytic origin; two others exhibited no markers and were designated "null" cells. All 10 DHL lines studied to date, as well as SU-DUL-1, were devoid of Epstein-Barr virus (EBV) genomes by the EB nuclear antigen test, whereas 2/3 AmB lines were positive. Spontaneous production of a C-type RNA virus was first detected in the postmitochondrial cytoplasmic fractions and culture fluids of SU-DHL-1. Screening assays for the detection of reverse transcriptase (RT)-positive particles in the culture fluids of the other cell lines indicate that 8/15 cell lines tested spontaneously initiated C-type RNA virus production. After partial purification by ion-exchange and affinity chromatography, the RT of the virus isolated from SU-DHL-1 cells is partially inhibited by antibodies to the RT's of C-type viruses of subhuman primate and endogenous feline, but not of murine, origin. Conversely, antibody prepared against the purified SU-DHL-1 viral RT, at concentrations that maximally inhibit the homologous enzyme, partially inhibits the RT's of subhuman primate C-type viruses, but has little or no inhibitory activity against the RT's of feline or murine leukemia viruses. The viruses produced by SU-DHL-1 and SU-AmB-3 are infectious for normal human peripheral blood mononuclear cells, normal human bone marrow cells, and certain human lymphoblastoid cell lines. After infection by these viruses, the mononuclear and bone marrow cells exhibit striking changes in growth behavior and morphology that, although not permanently sustained, have many of the features of abortive transformation. 79-1650 Hepatocellular Carcinoma in the USA, Etiologic Considerations. Localization of Hepatitis B Antigens. (Eng) Omata, M. (Sch. Medicine, Univ. Southern

California, Los Angeles, CA); Ashcava, M.; Liew, C. T.; Peters, R. L. *Gastroenterology* 76(2): 279-287; 1979.

The serologic and tissue markers of hepatitis B virus (HBV) were studied in 50 patients in whom hepatocellular carcinoma (HCC) was confirmed at autopsy. Fifteen of 20 patients with nonalcoholic chronic liver disease and HCC showed at least one marker of HBV infection including serum hepatitis B surface antigen (HBsAg) in 11 patients and tissue hepatitis B core antigen (HBcAg) in 10. Of 22 patients with alcoholic cirrhosis and HCC, 2 showed evidence of HBV infection. The incidence of HBV markers among 63 alcoholic cirrhotic patients without HCC was 7.9%. One of eight patients with HCC and otherwise normal livers had HBsAg and serum antibody to HBcAg; this patient was a former drug user. Of 321 patients in another autopsy series who had died with moderate to advanced alcoholic cirrhosis, 22 had HCC. Of 39 patients who had died with B-viral chronic liver disease, 15 had HCC. The data indicate that there is a high incidence of HBV among HCC patients with nonalcoholic chronic liver disease in the US. If chronic active hepatitis type B were as common in the US as it is in Africa and Asia, the incidence of HCC might also be as high. (37 refs)

79-1651 Hepatocellular Carcinoma in a Hepatitis B Surface Antigen Carrier and Treatment with Adriamycin. (Eng) Fung, W. P. (Univ. Dept. Medicine, Royal Perth Hosp., Box X2213 GPO, Perth 6001, Western Australia, Australia); Surveyor, I.; Scott, G. R.; Laden, A. M. *Am J Gastroenterol* 70(4): 397-400; 1978.

A hepatocellular carcinoma (HCC) occurred in a 32-yr-old Caucasian male carrier of hepatitis B surface antigen (HBsAg). The patient was also positive for α -fetoprotein, but he was negative for hepatitis B surface antibody. Adriamycin (60 mg iv) was given four times at intervals of 3-6 wk. HBsAg and α -fetoprotein remained positive, and there was no significant change in tumor size or significant clinical improvement. The patient died 7 mo after confirmation of HCC. Postmortem examination showed numerous nodules of HCC with multiple foci of necrosis; the liver was fibrotic and cirrhotic. HBsAg has frequently been reported in patients with HCC, and familial clustering of HCC and HBsAg has been found. The present case further supports the hypothesis that hepatitis B virus may be involved in the cause of HCC. (17 refs)

79-1652 Hepatitis B Virus Antigens in Primary Hepatic Carcinoma: Immunofluorescent Techniques on Fixed Liver Tissue. (Eng) Trevisan, A. (Istituto di Medicina Clinica, Cattedra di Patologia Medica dell'Universita di Padova, Padova, Italy); Realdi, G.; Losi, C.; Ninfo, V.; Rugge, M.; Rampinelli, L. *J Clin Pathol* 31(12): 1133-1139; 1978.

Immunofluorescence techniques were used to determine the presence of hepatitis B surface antigen (HBsAg) and core antigen (HBcAg) in liver specimens obtained at necropsy

from 107 patients (77 men, 30 women aged 1-93 yr) with primary hepatocellular carcinoma (HCC). HBsAg was detected in the nonneoplastic liver tissue of 16 patients: 13 with Grade I, 2 with Grade II, and 1 with Grade III HCC. Cirrhosis was present in 11/16 patients, and the remaining 5 showed underlying chronic active hepatitis (3) or nonspecific reactive hepatitis (2). HBsAg-positive cells were scattered among the patients with cirrhosis or chronic active hepatitis, but a sheet distribution was found in the latter. HBsAg was also present in the cytoplasm of the cancer cells in eight patients (all Grade I). The number of HBsAg-containing cells was lower in the neoplastic tissue than in normal tissue. HBcAg in a granular pattern was detected in the nuclei of nonneoplastic cells in eight patients (6 Grade I, 1 Grade II, 1 Grade III); in six of these patients, HBcAg was also found in scattered nuclei in the neoplastic cells. In two other patients, which were negative for HBcAg but positive for HBsAg in nonneoplastic tissue, many cancer cells showed a positive nuclear reaction with anti-HBc serum. The nuclear pattern of HBcAg in neoplastic tissue was similar to that observed in the normal cells. Thus, hepatitis B virus (HBV) markers were detected mainly in the liver of patients with a well-differentiated tumor, and in all of these cases HBsAg and/or HBcAg were found also in the malignant cells. Although the tumor cells could have been infected after malignant transformation, a direct oncogenic role of HBV cannot be excluded. (21 refs)

- 79-1653 Sequence Analysis of Adenovirus DNA. I. Nucleotide Sequence at the Carboxy-terminal End of the Gene for Adenovirus Type 2 Hexon.** (Eng) Akusjarvi, G. (Dept. Microbiology, Univ. Uppsala, Biomedical Center, Box 581, S-751 23 Uppsala, Sweden); Pettersson, U. *Virology* 91(2): 477-480; 1978.

Adenovirus type 2 (Ad2) DNA was cleaved with restriction endonucleases *Bam*HI and *Bgl*II, and the nucleotide sequence of a 210-base pair fragment located between map positions 59.0 and 60.2 was determined. The sequence included a terminator, UAA, located within an AT-rich region 136-138 nucleotides to the right of the *Bam*HI cleavage site at position 59.0. A nearly perfect inverted repeat of this region occurred in a segment starting 22 nucleotides to the right of the *Bam*HI cleavage site. The codons immediately preceding the termination codon determined the sequence Thr-Pro-Phe-Ser-Ala-Gly-Asp-Ala-Thr-Thr. The established sequence thus included the codons for the 45 C-terminal amino acids of the Ad2 hexon and 75 nucleotides from the presumptive noncoding 3'-terminal part of the hexon messenger RNA. In the C-terminal part of the hexon gene, 75.6% of the coding triplets terminated with a C or, less commonly, a G; only 3/45 codons ended with an A. (9 refs)

- 79-1654 Mapping of the DNA Fragments Produced by Cleavage of *Eco*RI F Fragment of Adenovirus 2 with *Hae*III, *Hpa*II and *Alu*I.** (Eng) Herisse, J. (Laboratoire d'Hématologie Experimentale, Centre Hayem-Hopital Saint-Louis, 75475 Paris Cedex 10, France); Courtois, G.; Galibert, F. *Gene* 4(4): 279-294; 1978.

The physical map of the cleavage sites of several restriction endonucleases for the adenovirus 2 *Eco*RI F fragment was established. Hydrolysis of this fragment with *Hae*III, *Hpa*II, and *Alu*I gave 9, 11, and 11 fragments, respectively. Their size ranged from 20 base pairs for the smallest *Hpa*II K fragment to 585 base pairs for the largest *Alu*I A fragment. The order of the fragments was deduced mainly from partial hydrolysis analyses. The relative order of all restriction sites and the distance in nucleotides between them were obtained by secondary hydrolyses of each restriction fragment by the other two enzymes. The position of the *Kpn*I, *Hind*III, *Mbo*I, and *Sma*I sites within the *Eco*RI F fragment was also determined. (16 refs)

- 79-1655 Regulation of an Early RNA Transcribed from the Transforming Segment of the Adenovirus 2 Genome.** (Eng) Eggerding, F. (Dept. Pathology, Univ. California, Center Health Sciences, Los Angeles, CA, 90024); Raskas, H. J. *Virology* 91(2): 312-320; 1978.

Studies that suggest that the cytoplasmic concentration of the 22S messenger RNA (mRNA) is regulated by a second mechanism that supplements the coordinate regulation of the other major early mRNA's are presented. Early cytoplasmic RNA transcribed from the left end of the adenovirus 2 genome (region 1) is composed of two major size classes that migrate as 22S and 13S RNA's. Previous studies have shown that treatment with inhibitors of protein synthesis such as cycloheximide (CH) resulted in a significantly increased (10-fold) accumulation of all major size classes of cytoplasmic early RNA except a 22S species encoded by region 1. To clarify this differential effect of CH, the metabolism of region 1 RNA was compared in several experiments. The kinetics of accumulation of these RNA's in the absence of drug was analyzed beginning 3 hr after infection. The 13S size class accumulated more rapidly than the 22S RNA; after 2 hr of labeling, there was a threefold excess of 13S RNA compared with cultures labeled for 3 hr. Chase experiments using either actinomycin D in the absence of CH or cold uridine when CH was present demonstrated that the 22S RNA was more stable than the 13S size class. Thus, a 22S species is unlikely to serve as precursor to a major smaller RNA. Early RNA's synthesized in the presence of the amino acid analogs canavanine or β -hydroxynorvaline also contained increased amounts of region 1 13S RNA but not the 22S size class. To determine the effect of delayed CH addition, infections were performed in the absence of inhibitors and CH was then added 4 hr later. Under these conditions, the 22S RNA synthesized from 4.5 to 6.5 hr accumulated in increased amounts, comparable to the other early RNA's. The results suggest that a protein synthesized early in infection regulates the cytoplasmic concentration of 22S RNA. (33 refs)

- 79-1656 Splicing Patterns of Nuclear Precursors to the mRNA for Adenovirus 2 DNA Binding Protein.** (Eng) Goldenberg, C. J. (Dept. Pathology, Div. Biology, Bi-

omedical Sciences, Washington Univ. Sch. Medicine, St. Louis, MO, 63110); Raskas, H. J. *Cell* 16(1): 131-138; 1979.

The relationship of nuclear and cytoplasmic RNA's from early region 2 of the adenovirus 2 (Ad2) genome (map positions 61.6-75.0) was determined. Structural analysis demonstrated that nuclear 23S and 20S RNA's lack intervening sequences (map positions 74.6-68.8) that are also absent from the cytoplasmic messenger RNA (mRNA). The nuclear 28S RNA, however, has sequences complementary to the intervening DNA sequences. Analysis of colinear transcripts from the I strand of region 2 suggested that nuclear 28S and 23S RNA's contain the intervening sequences from a second splice (map positions 68.3-66.3). The nuclear 20S RNA and the mature cytoplasmic mRNA lack these sequences. Colinear polyadenylated transcripts were detected from the r strand of region 2; these transcripts have no apparent relationship to early mRNA. In continuous-labeling experiments, the 28S and 23S species reached a steady state within 30 min, whereas the amounts of nuclear and cytoplasmic 20S RNA's continued to increase for at least 3 hr. This labeling pattern suggests that the 28S and 23S species are precursors of the 20S RNA. A processing model for mRNA is proposed in which the intervening DNA sequences of the 72K DNA binding

protein gene are transcribed in its mRNA precursor (28S). These sequences are then removed sequentially to generate first a 23S intermediate and then a 20S nuclear RNA that will be transported to the cytoplasm as a mature mRNA. (48 refs)

- 79-1657 Tumor Metastases and Cell-mediated Immunity in a Model System in DBA/2 Mice. IV. Antigenic Differences Between a Metastasizing Variant and the Parental Tumor Line Revealed by Cytotoxic T Lymphocytes.** (Eng) Schirmacher, V. (Institut für Immunologie und Genetik, Deutsches Krebsforschungszentrum, Heidelberg, W. Germany); Bosslet, K.; Shantz, G.; Clauer, K.; Hubsch, D. *Int J Cancer* 23(2): 245-252; 1979.

The syngeneic cytotoxic T-cell response against a metastasizing murine lymphoma variant (ESb) was investigated and compared with the response against the nonmetastasizing parental tumor line Eb. Antitumor cytotoxicity (ATC) was not detectable in a 4-hr ^{51}Cr -release assay in spleens taken directly from tumor-bearing animals [primary cell-mediated cytotoxicity (CMC)]. After restimulation in vitro (secondary CMC), however, high ATC was detected. This activity was mediated by immune T lymphocytes, as shown by its sensitivity to treatment with anti-Thy 1.2 serum and complement. Ten cells of the metastasizing tumor ESb, inoculated sc, were sufficient to raise a local tumor and metastases and to induce cytotoxic T memory cells in the spleens. In contrast, about 10^4 Eb cells were required to raise a local tumor and to induce splenic cytotoxic T memory cells. Specificity studies of the ATC demonstrated that cytotoxic T cells could distinguish unrelated, chemically induced syngeneic tumors and also recognize antigenic differences between the parental tumor Eb and its variant ESb. Eb and ESb tumor cells were recognized as carrying distinct antigens at the responder cell level, the stimulator cell level, and the target cell level. The in vivo significance of these findings is discussed. (47 refs)

- 79-1660 Pregnancy, Breast-Cancer Risk, and Maternal-Fetal Genetics (Letter to Editor).** (Eng) Janerich, D. T. (New York State Dept. Health, Cancer Control Bureau, Albany, NY, 12237). *Lancet* 1(8111): 327-328; 1979.

Evidence suggests that pregnancy may have adverse as well as beneficial effects on the risk of breast cancer. It is hypothesized that suppression of the immune system during pregnancy stimulates the growth of latent tumors, most of which are destroyed when the immune system returns to normal after pregnancy. Some tumors, however, may become too established during pregnancy to be destroyed afterward, resulting in the higher rate of breast cancer observed in married women aged 25-40 yr. (5 refs)

- 79-1661 Activated Macrophages Digest the Extracellular Matrix Proteins Produced by Cultured Cells.** (Eng) Jones, P. A. (Div. Hematology-Oncology, Childrens Hosp. of Los Angeles, 4650 Sunset Blvd., Los Angeles, CA, 90027); Scott-Burden, T. *Biochem Biophys Res Commun* 86(1): 71-77; 1979.

The degradation by activated mouse peritoneal macrophages of the extracellular matrix proteins produced by cultured smooth muscle cells was studied. The smooth muscle cells, obtained from culture passages 4-8, were incubated with ^3H -proline, which resulted in the synthesis of an extensive radioactively labeled matrix. The producer cells were removed from the culture dishes by mild alkaline treatment, and the activated macrophages were cultured on the matrix with various serum supplements. The digestion rate was dependent on the serum supplement, with the slowest degradation occurring under serum-free conditions and the most rapid in the presence of dog serum, which contains high levels of plasminogen (PMG). The presence of PMG caused a considerable stimulation of hydrolysis, especially under serum-free conditions with added PMG. The supernatant medium from dishes containing macrophages plated on ^3H -proline-labeled matrices was analyzed by Sephadex G-25 gel filtration. After 24 hr, a small amount of radioactivity eluted in the position in which ^3H -proline eluted from the column; the percentage of radioactivity in this position increased linearly with time. The results show the macrophages produce enzymes capable of digesting the matrix and that macrophage PMG activator has a major role in this digestion. (16 refs)

- 79-1662 Effects on In Vitro Tumor Growth of Macrophages Isolated from Human Ascitic Ovarian Tumors.** (Eng) Mantovani, A. (Istituto di Ricerche Farmacologiche "Mario Negri", Via Eritrea 62, 20157 Milan, Italy); Peri, G.; Polentarutti, N.; Bolis, G.; Mangioni, C.; Spreafico, F. *Int J Cancer* 23(2): 157-164; 1979.

Macrophages (MP's) were isolated from 22 human ascitic ovarian epithelial tumors, and their growth-inhibitory

capacity was tested using the following in vitro tumor cell lines as targets: murine TLX9 lymphoma and FS6 sarcoma; human myeloid K562 leukemia and a human E-cell line derived from an ovarian carcinoma. MP preparations were heterogeneous in their interaction with tumor target cells, and assay conditions, such as the type of target cell, incubation time, and attacker to target cell (A:T) ratio, critically affected the evaluation of the cytotoxic potential of tumor-associated MP's. At an A:T ratio of 7:1, no cytostatic activity on TLX9 and K562 cells was ever observed, but in the presence of specific antibody, 8/12 MP preparations tested showed significant antibody-dependent cytotoxicity on TLX9 lymphoma cells. MP preparations from two patients significantly inhibited growth of the FS6 sarcoma, and a cytostatic activity on E cells was observed in five additional patients. Significant stimulation of the proliferative capacity of at least one of the target cell lines was observed in 11 subjects at an A:T ratio of 7:1. In 12 patients, MP cytostatic activity on E cells was also tested at an A:T ratio of 35:1; 8/12 preparations showed significant cytotoxicity under these conditions. When the same subject was repeatedly tested at short intervals, the same pattern of inhibition or stimulation of tumor growth was observed. (35 refs)

79-1667 Enhancement Versus Tumor Resistance Induced by Different Levels of Immunodepression in BALB/c Mice with Protozoan Infections. (Eng) Landolfo, S. (Dept. Microbiology, Univ. Turin, Via Santena 9, 10126

Turin, Italy); Giovarelli, M.; Martinotti, M. G.; Varesio, L.; Cappuccinelli, P. *Eur J Cancer* 15(1): 27-33; 1979.

The relationship between the immunodepression induced by infection with *Trypanosoma congolense* (TC) or *Trichomonas vaginalis* (TV) and in vivo resistance to the growth of a spontaneous syngeneic mammary adenocarcinoma (ADK/lt) was evaluated in BALB/c mice. Mice were challenged with $\times 0.1$ ml of a suspension containing 10^8 sheep RBC 7, 20, 28, and 39 days postinfection (PI). The number of plaque-forming cells and the hemolytic and hemagglutinating antibody titers were reduced 12 days PI in TV-infected (TVI) mice. Thereafter, the response returned to control levels. TCI animals showed a marked decrease in all three parameters throughout the 10-wk experiment. At 8 days PI, all infected mice exhibited a marked depression of the cellular response to oxazolone compared with controls; however, a return to normal levels occurred on day 15 in TVI mice and on day 29 in TCI mice. The spleen cell response to phytohemagglutinin was depressed significantly between days 8 and 15 in both infected groups; however, normal levels were reached by day 22 in TVI mice vs day 29 in TCI mice. Tumor incidence and growth were evaluated in control and infected mice inoculated with 10^5 ADK/lt cells (1 wk PI in the latter). Initially, tumor incidence was slightly higher in TVI mice vs controls; this difference disappeared between 28 and 32 days after tumor injection when a 100% incidence occurred in both groups. Tumor growth rate and tumor mass were higher in TVI mice than in controls. In TCI animals, however, tumor take was much lower than that in controls and a 100% incidence was reached 18-20 days after it occurred in controls. Tumor growth in these mice was consistently slower than that in the other two groups. It is concluded that low or high levels of immunodepression, probably related to low or high levels of macrophage activation, appear to induce different patterns of tumor growth. (42 refs)

79-1670 Significance of Immunosuppression for Tumor Growth and Spread. (Ger) Dorschner, W. (Urologische Klinik, Karl-Marx-Universität Leipzig, Liebigstrasse 21, DDR-701 Leipzig, E. Germany); Schonfelder, M. *Z Urol Nephrol* 71(10): 747-752; 1978.

The effect of immunosuppression on the transplantability of human melanoblastoma and breast carcinoma cells was studied in male and female Wistar rats. The tumors cells (2×10^6 /animal) were transplanted iv, ip, or sc after immunosuppression was achieved by methotrexate (MTX: 1 mg/wk x 2, then 0.5-0.25 mg/wk, im; av total dose, 5 mg/animal). Some animals also received azathioprine (av total dose, 5 mg/animal) after tumor transplantation. The controls received MTX or tumor cells only. The animals were autopsied 2 days to 6 wk after tumor cell transplantation. Fifteen of 44 controls treated with MTX only died of infection or hemorrhage. These controls had severe signs of hepatotoxicity and nephrotoxicity, a depleted bone marrow, and a nearly complete absence of round cells in the spleen. The animals treated with MTX with and without azathioprine developed liver and lung metastases, but tumor growth lasted only as long as the immunosuppressive effect. The animals that did not receive immunosuppressive treatment did not develop tumors after transplantation. (no refs)

- 79-1671 Effector and Suppressor Lymphoid Cells in Tumor-bearing Guinea-Pigs.** (Eng) Berci, I. (Dept. Immunology, Univ. Manitoba, Winnipeg, Manitoba R3E OW3, Canada); Schon, A. H. *Int J Cancer* 23(2): 274-282; 1979.

The immune reaction of guinea pigs against their growing tumors was studied. Strain 13 guinea pigs were killed 2 wk after sc implantation of a transplantable methylcholanthrene-induced sarcoma (MC-D), when the tumor was 2-3 cm in diameter. Spleen, lymph node, and bone marrow cells, peripheral blood leukocytes (PBL), and subsets of spleen cells and PBL were mixed with lethal doses (10^5) of tumor cells and inoculated sc into normal recipients. Spleen, lymph node, and bone marrow cells either enhanced or did not influence tumor growth, but PBL exerted a strong inhibitory effect. Normal spleen and normal PBL did not affect tumor growth. The spleen cells of tumor-bearing animals were separated on nylon wool columns: the first fraction containing T cells was responsible for tumor enhancement, the second fraction containing predominantly non-T (Ia+) cells inhibited tumor growth. Adherent cells had no effect. Similarly, after removal of T cells from the spleens with a specific rabbit antiserum or of non-T cells plus a minor portion of T cells with an anti-Ia serum (produced in strain 2 guinea pigs), the remaining cell population had, respectively, an inhibitory or an enhancing effect on tumor growth. By contrast, removal of either T or Ia+ cells from PBL eliminated their antitumor effect. The major portion of splenic T cells formed erythrocyte-antibody (EA) rosettes. EA rosette-positive cells were restricted to a minor portion of the peripheral T lymphocytes. Thus, splenic and peripheral T cells from tumor-bearing animals were different both functionally and according to their surface markers. Fc+ T cells are hypothesized to be suppressors that are triggered by immune complexes. (42 refs)

- 79-1674 Immunoglobulin-producing Cells in the "Transitional" Mucosa Adjacent to Adenocarcinomas of the Human Large Bowel.** (Eng) Rognum, T. O. (Histological Lab., Inst. Pathology, University Hosp., Oslo, Norway); Brandtzaeg, P.; Baklien, K.; Hognestad, J. *Int J Cancer* 23(2): 165-173; 1979.

IgA-, IgM-, and IgG-producing immunocytes were quantitated in a defined mucosal tissue unit adjacent to 16 adenocarcinomas of the large bowel, and the data were compared with data for control units from 15 histologically normal specimens. The thickness of the "transitional" mucosa adjacent to the tumors was markedly increased. Thus, the av cancer-associated unit showed a 2.6-fold increase in height and its number of immunoglobulin-producing cells was raised 2.8 times. The numerical increase for IgA cells was 2.1, for IgM cells 5.1, and for IgG cells 13.0; the percentage proportions of these cell classes were changed from 91:6:3.6 to 71:12:17. Only very rare IgD- and IgE-producing cells were seen. The immunocyte density in 6- μ m-thick sections (cell number/mm² of lamina propria) was 823, 136, and 201 for the IgA, IgM, and IgG class, respectively, compared with the normal figures of 1,186, 73, and 49. The density of IgG and IgM cells was thus significantly increased and that of IgA cells decreased in the lamina propria of the "transitional" mucosa. The intraindividual scatter of all variables, including mucosal height, was large in the "transitional" mucosa, but the variables became normalized approx 1 cm from the tumor. The excessive rise in the local production of IgG, with no concomitant increase in the density of IgA cells, indicates that there are local stimulatory factors bypassing the secretory IgA immune system. Further studies are needed to show if this local immune response reflects the production of tumor-specific antibodies or is merely due to the increased penetrability of antigens from the gut lumen through the tumor lesion. - 79-1675 Systemic Lupus Erythematosus and DNA Antibodies in Pleural Effusions.** (Eng) Riska, H. (Mjølbolsta Hosp., 103 50 Mjølbolsta, Finland); Fyhrquist, F.; Selander, R. K.; Hellstrom, P. E. *Scand J Rheumatol* 7(3): 159-160; 1978.

High binding of double-stranded DNA was observed in pleural fluid from five patients with systemic lupus erythematosus (SLE) and four with lung cancer. However, DNase treatment revealed that DNA-anti-DNA complexes in pleural fluid were confined to the SLE patients and were not present in pleural fluid from lung cancer patients. (5 refs)

79-1676 Human Brain Tumor Transplantation into Nude Mice. (Eng) Shapiro, W. R. (George C. Cotzias Lab. Neuro-Oncology, Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY, 10021); Basler, G. A.; Chernik, N. L.; Posner, J. B. *J Natl Cancer Inst* 62(3): 447-453; 1979.

Seven human brain tumors were transplanted into the brains (6/7 takes) and sc tissues (7/7 takes) of inbred Swiss athymic nude mice. Compared with experimental animal brain tumors, these tumors, taken directly from patients in the operating room and transplanted, grew more slowly in the mice. Their growth rates following explant generally paralleled those in the patients. A rough correlation was seen between degree of tumor malignancy and both successful take rate and rate of growth following explant. Growth rates increased during serial transplantation after explant. Two tumors developed into long-term serial lines; both came from gliosarcomas. Preliminary chemotherapy experiments with these two lines demonstrated differential chemosensitivities. One line was very sensitive to several nitrosoureas and resistant to procarbazine; the other was more sensitive to procarbazine than to the nitrosoureas. This model permits study of the biologic behavior of human brain tumors growing intracerebrally and sc in nude mice. (20 refs)

79-1677 A Genetic Basis for the Susceptibility of Rabbits to the VX2 Tumor (Meeting Abstract). (Eng) Lancki, D. W. (Univ. Illinois Medical Center, Chicago, IL, 60680); Tissot, R. G.; Cohen, C. *Fed Proc* 38(3, part 2): 1104; 1979. (no refs)

79-1678 The Presence of F9 Antigen on the Surface of Mouse Embryonic Cells Until Day 8 of Embryogenesis. (Eng) Buc-Caron, M. H. (Service de Genetique cellulaire, College de France, Institut Pasteur, 25 rue de Dr Roux 75015, Cedex 15, Paris, France); Condamine, H.; Jacob, F. *J Embryol Exp Morphol* 47: 149-160; 1978.

The presence of F9 antigen on the cell surface of mouse embryos was examined by anti-F9 serum absorption and indirect immunofluorescence staining tests. Pregnant strain 129/Sv mice were killed on day 7, 8, or 9 of pregnancy, and embryonic cell suspensions were prepared. F9 antigen was readily detected by both methods on the surface of 7- and 8-day-old embryonic cells but not on 9-day cells. An anti-F9 serum that absorbed with 8-day (but not with 9-day) embryonic cells did not react with 2-day embryos (morulae). The major histocompatibility (H-2) antigen was demonstrable on 9-day

cells but not on 8-day cells. In immunofluorescence staining experiments, labeling occurred in >95% of the cells from 7-day embryos, 58% of the cells from 8-day embryos, and essentially none from 9-day embryos. It is concluded that the antigenic determinants that are recognized on the surface of morulae by the anti-F9 serum are also present on 8-day embryos but not on 9-day embryos. They are either absent, masked, or quantitatively reduced. (24 refs)

79-1683 Characterization of a Leukemic Cell Line of the Pre-B Phenotype. (Eng) Hurwitz, R. (Dept. Pediatrics, Univ. Minnesota, Minneapolis, MN, 55455); Hozier, J.; LeBien, T.; Minowada, J.; Gajl-Peczalska, K.; Kubonishi, I.; Kersey, J. *Int J Cancer* 23(2): 174-180; 1979.

The characteristics of NALM-6-M1, one of eight leukemia cell lines cultured from the peripheral blood of a 19-yr-old boy with non-T, non-B acute lymphoblastic leukemia in relapse, are presented. This cell line was found to be >90% cytoplasmic immunoglobulin positive (cIg+) for both mu heavy and lambda light chains, but surface immunoglobulin and complement receptor negative. NALM-6-M1 was cIg- for alpha, delta, and gamma heavy chains and kappa light chain. About 45% of the cells exhibited sheep RBC receptors. Approx 12% of the cells were positive for Fc receptors. Approx 90% of the cultured cells had a deleted long arm of chromosome 5 (5q-) and a marker Y chromosome. The remaining 10% of cells had some additional chromosomal

material on the long arm of chromosome 12, suggesting a partial translocation. No other karyotypic abnormalities were found. The cell line reacted strongly with anti-p23,30, suggesting Ia-like activity, but it only weakly stimulated normal lymphocytes in mixed leukocyte culture. The cells expressed HLA antigens. NALM-6-M1 failed to react with anti-thymocyte serum, did not possess Epstein-Barr membrane or nuclear antigens, and did not exhibit phagocytosis for zymosan. NALM-6-M1 reacted positively with Oil Red O and Sudan black stains. The cIgM staining indicates that NALM-6-M1 is arrested at an early stage in B-cell development. This cell line is considered to be of the pre-B-cell phenotype possessing a chromosomal abnormality. (27 refs)

- 79-1684 Idiopathic Paraproteinemia. II. Transplantation of the Paraprotein-producing Clone from Old to Young C57BL/KaLwRij Mice.** (Eng) Radl, J. (Inst. Experimental Gerontology of the Organization Health Res. TNO, 151, Lange Kleiweg, Rijswijk, Netherlands); De Glopper, E.; Schuit, H. R.; Zurcher, C. *J Immunol* 122(2): 609-613; 1979.

Bone marrow and/or spleen cells from old C57BL mice with idiopathic paraproteinemia (IP) were transplanted into young syngeneic mice with a normal heterogenous immunoglobulin pattern to determine whether factors intrinsic or extrinsic to the immune system and to the paraprotein-producing cell clone are responsible for IP. In 9/10 experiments, the IP-producing clone "took" in the recipients. The take frequency was the same in irradiated and nonirradiated recipients, but the paraprotein was generally detected 1-3 mo earlier in the irradiated mice. Cells from the mesenteric lymph node of a mouse with IP were less efficient in inducing IP in normal recipients, and the cell-free extract of bone marrow or spleen cells was not effective. Propagation of IP for three to four transplant generations seemed to be the final limit: the av take frequency for generations 1-4 was 63%, 51%, 23%, and 4%, respectively. Transplantation of cells from mice with a lymphoreticular malignancy resulted in a continuous propagation of the malignancy, with a high take frequency, progressive development of the paraproteinemia, and a shortened recipient survival time. The data indicate that IP represents in its final stage in the aging C57BL mouse, an intrinsic defect within the affected B-cell clone and that this defect differs from that found in B-cell malignancies. - 79-1685 Tumor Induction in Host-vs-Graft Disease (HVGD) II. Immunologic and Virologic Features (Meeting Abstract).** (Eng) Cornelius, E. (Yale Univ., New Haven, CT, 06510). *Fed Proc* 38(3, part 2): 992; 1979. (no refs)

- 79-1686 Establishment and Characterization of BALB/c Lymphoma Lines with B Cell Properties.** (Eng) Kim, K. J. (Lab. Microbial Immunity, Natl. Inst. Allergy and Infectious Diseases, NCI, NIH, Bethesda, MD, 20014);

Kanellopoulos-Langevin, C.; Merwin, R. M.; Sachs, D. H.; Asofsky, R. *J Immunol* 122(2): 549-554; 1979.

Five spontaneously derived BALB/c tumors (K46, X16C, L10A, A20, and M12) and one 1-ethyl-1-nitrosourea-induced BALB/c tumor (BALENLM 17) were established in culture and characterized according to their surface markers. L10A, X16C, K46, and BALENLM 17 were found to bear IgM, Fc receptors, and I-region-associated (Ia) antigens. A20 expressed Fc receptors and Ia antigens, and M12 had only Fc receptors. All lines bore surface immunoglobulin (Ig) and none bore complement receptors. Although all lines stained with intact molecules or with F(ab')₂ fractions of polyvalent anti-mouse Ig antibodies, staining of M12 with these agents was faint. None of the six lines phagocytized latex particles, all were negative for Thy 1.2 antigen, and they grew as stationary suspension cultures. Therefore, these six BALB/c lymphoid lines are presumably of B-cell origin at various stages of differentiation. The chromosome numbers of L10A, K46, and X16C were hypotetraploid, whereas those of BALENLM 17, A20, and M12 were near diploid. The generation times of the lines ranged from 18 to 26 hr. After > 6 mo in culture, all cell lines except X16 were tumorigenic in BALB/c mice within 1 mo. (40 refs)

- 79-1687 Tumor Metastases and Cell-mediated Immunity in a Model System in DBA/2 Mice. I. Tumor Invasiveness In Vitro and Metastasis Formation In Vivo.** (Eng) Schirmacher, V. (Institut für Immunologie und Genetik, Deutsches Krebsforschungszentrum, Heidelberg, W. Germany); Shantz, G.; Clauer, K.; Komitowski, D.; Zimmermann, H. P.; Lohmann-Matthes, M. L. *Int J Cancer* 23(2): 233-244; 1979.

Tumor metastases and cell-mediated immunity were studied in a syngeneic model system in DBA/2 mice. The system consisted of two related methylcholanthrene (MC)-induced murine lymphomas, the nonmetastasizing parental line Eb and its metastasizing variant ESb. An unrelated MC-induced tumor (MDAY) was included for specificity controls. Serological typing revealed that Eb and ESb were of T-lymphoid origin and that they expressed the H-2K and H-2D molecules of the host strain (DBA/2). By various electron microscope techniques, morphological differences were observed between the two cell lines. ESb tumor cells had a more polymorphic nucleus with many invaginations of the nuclear envelope and a more prominent expression of microvilli on the cell surface. An in vitro organ culture test for tumor invasiveness, presented here for the first time in a syngeneic murine system, revealed that ESb but not Eb cells had the ability to attach to and invade normal tissue. Accordingly, ESb cells showed higher malignancy in vivo. This was apparent from their higher tumorigenicity and their ability to disseminate and metastasize and to kill recipient mice more quickly. Upon histological examination of the local primary tumors, a striking difference was noticed with regard to the degree of infiltration by host-derived mononuclear cells, mostly histiocytes. The nonmetastasizing tumor Eb was heavily infiltrated, but

tumor ESb contained only a few of these cells. The differences between ESb and Eb are considered in the light of their possible relevance for metastases in general. (46 refs)

79-1688 Protein Patterns of Normal and EBV-Genome Positive Human B Lymphocytes (Meeting Abstract). (Eng) Bachvaroff, R. J. (Dept. Surgery, State Univ. New York at Stony Brook, Stony Brook, NY, 11594); Rapaport, F. T. *Fed Proc* 38(3, part 2): 1369; 1979. (no refs)

79-1689 Discordance of Epstein-Barr Virus (EBV) Specific Humoral and Cellular Immunity in Patients With Malignant Lymphomas: Elevated Antibody Titres and Lowered In Vitro Lymphocyte Reactivity. (Eng) ten Napel, C. H. (Dept. Medicine, Univ. Hosp., Oostersingel 58, Groningen, Netherlands); The, T. H.; Van Egten-Bijker, J.; De Gast, G. C.; Halie, M. R.; Langenhuisen, M. M. *Clin Exp Immunol* 34(3): 338-346; 1978.

The relationship between specific viral cellular and humoral immunity to Epstein-Barr virus (EBV) was studied in 17 untreated patients with Hodgkin's disease (HD: age 9-61 yr; median 30), 14 untreated patients with non-Hodgkin's lymphoma (age 21-81 yr; median 59), and 31 age- and sex-matched healthy controls. Antibodies to EBV virus capsid antigens (EBV-VCA) were present in 29/31 malignant lymphoma (ML) patients, and all controls were seropositive. The geometric mean titer (GMT) was markedly higher in the HD patients (3,180) than in the controls (924). The GMT of the non-Hodgkin's lymphoma patients was not significantly raised compared with that of controls (1,424 vs 861). EBV-induced lymphocyte reactivity (EBV-LR) was markedly lower in the ML patients, especially those with HD, than in the controls. Ten of 13 of the controls with EBV-VCA antibody titers > 640 were positive for EBV-LR, compared with only 30% of the ML patients and 30% of the HD pa-

tients. LR to antigen cocktail (containing diphtheria and tetanus toxins, *Candida albicans* antigens, and purified protein derivative) and mitogen stimulation was lower in ML patients than in controls, but most patients showed responses within the normal range. There was no correlation between LR to EBV and general LR to antigens and mitogens. General LR did not differ in EBV-seropositive patients with positive EBV-LR and those with negative EBV-LR. The results support the hypothesis that depressed cellular immunity may cause raised EBV antibodies in ML, especially in HD. (33 refs)

- 79-1691 Sex Chromosome Aberrations Involving Loss and Translocation of Tumor-inducing Loci in *Xiphophorus*. (Eng) Ahuja, M. R. (Genetisches Institut, Justus-Liebig-Universität Giessen, Heinrich-Buff-Ring 58-62, D-6300 Giessen, W. Germany); Lepper, K.; Anders, F. *Experientia* 35(1): 28-30; 1979.

The cytologic nature of (1) a deletion involving the Sd (spotted dorsal fin) locus and (2) an X-Y translocation involving the Sr (striped sides of body) locus of the platyfish, *Platyplecillus* (*Xiphophorus*) *maculatus*, was investigated, along with the genetic consequences of these aberrations on the tumor potential and viability of the fish. Analysis of the Sd deletion revealed a loss of one of two major terminal Giemsa bands of the X-chromosome. The fragment lost due to deletion was approx 0.3-0.5 μ m long, or up to one-quarter of the chromosome. The genetic consequences of this deletion are that neither males nor females exhibit black spots on the dorsal fin and they do not develop melanomas on the dorsal fin after exposure to a chemical carcinogen. Karyotypic analysis of the X-Y translocation revealed that the Sr fragment is probably translocated to the end of the normal arm of the X-chromosome. The phenotypic consequence of this translocation is that both sexes are stripe-sided. Females do not develop melanomas, suggesting that the controlling gene that governs the expression of Sr is translocated along with Sr and closely linked to it. Impairment or deletion of tissue-specific regulating genes presumably leads to neoplasia, whereas loss or impairment of the tumor-inducing loci (eg, Sr or Sd) would lead to loss of tumor-inducing potential in a specific tissue. (19 refs)

- 79-1692 Karyotypic Evolution Associated with Loss of Tumorigenicity. (Eng) Shepard, J. S. (Dept. Pathology, Dartmouth Medical Sch., Hanover, NH, 03755); Pettengill, O. S.; Wurster-Hill, D. H.; Sorenson, G. D. *J Natl Cancer Inst* 62(3): 547-554; 1979.

The karyotypes and tumorigenicities (TG's: in normal and irradiated BALB/c mice) of two cell culture lines (SLU-5 and DMS-402) established from the mouse plasmacytoma MOPC-21 carried in BALB/c mice were followed for up to 70 mo after isolation. After 36 mo, SLU-5 cells were non-TG in normal BALB/c mice but were still TG in irradiated mice; by 64 mo, the culture was nonlethal in irradiated hosts. Although the number of chromosomes in this culture remained constant during 70 mo, each loss of TG was associated with a change in karyotype. Similar changes in karyotype and TG were observed in DMS-402, although TG decreased after 17 mo in culture. The data suggest that the cultures were heterogeneous and that new cell populations arose because of selection for cell types already present in the young cultures. Whe-

reas most markers remained constant in appearance during the culture period, m10 underwent successive intrachromosomal alterations, one for each qualitative change in TG. These marker changes were small and cryptic, were not easily explained as translocations, and looked more like specific regional alterations in chromosome coiling. The presumed original defect in chromosome 15, which has been specifically associated with mouse myelomas, was not corrected or eliminated when TG was lost. In conclusion, loss of TG was not an all-or-none phenomenon but a gradual or incremental process, and each change of potency was the outcome of natural selection for a new cell type. (20 refs)

- 79-1693 Transformation of Normal Diploid Cells by Isolated Metaphase Chromosomes of Virus-transformed or Spontaneous Tumor Cells. (Eng) Cassingena, R. (Institut de Recherches Scientifiques sur le Cancer, B.P. No. 8, 94800-Villejuif, France); Suarez, H. G.; Lavialle, C.; Persuy, M. A.; Ermonval, M. *Gene* 4(4): 337-349; 1978.

The in vitro transformation of a variety of normal diploid cells (human embryonic lung, Swiss mouse embryo, Wistar rat embryo) by metaphase chromosomes (CS's) isolated from various virus-transformed or spontaneous tumor cells was examined. The CS donors included cells from (1) human skin transformed by simian virus 40 (SV40), (2) WAG rat embryonic lung transformed by SV40, (3) human embryonic kidney transformed by sheared adenovirus 5 DNA, (4) A/Jax mouse neuroblastoma, and (5, 6, 7) human cervical carcinoma, lung carcinoma, and melanoma. Approx $1-3 \times 10^6$ recipient cells were mixed with $2-6 \times 10^7$ isolated CS's. After exposure to CS's from any of the three virus-transformed lines, both homologous and heterologous recipient cells were able to form colonies in selective soft agar and/or low serum medium. Colonies appeared with a frequency of 10^{-4} - 10^{-6} , the highest being observed in intraspecific transfers with CS's from SV40-transformed cells. When normal diploid cells were exposed to CS's from mouse or human tumor cells, every combination gave rise to colony formation in selective medium, with frequencies of 10^{-3} - 10^{-6} . CS's from normal diploid cells did not show any transforming activity. In general, transformation efficiency was higher for homologous than for heterologous transfers. A fraction of the colonies stopped growing and died after the third week. Nevertheless, using CS's from all but one donor cell population (human melanoma), at least one transformed cell line expressing a stable transformed phenotype was established. The results show that normal diploid cells can be transformed by a presumptive CS-mediated gene transfer with a variety of donor and recipient cells. (21 refs)

PATHOGENESIS

- 79-1694 Risk of Malignancy and Chromosomal Polymorphism: A Possible Mechanism of Association.** (Eng) Shabtai, F. (B. Gattegno Res. Inst. Human Reproduction and Fetal Development, Hasharon Hosp., Petah-Tiqva, Israel); Halbrecht, I. *Clin Genet* 15(1): 73-77; 1979.

The possible association of heterochromatic chromosomal variants and risk of malignancy was investigated in 120 patients (62 men, 58 women aged 14-78 yr) with malignant or premalignant hematologic diseases. The group comprised 30 patients with different types of acute leukemia, 20 with chronic myelocytic leukemia, 17 with polycythemia rubra vera, and 53 with a series of aplastic, hyperplastic, dysplastic, and metaplastic disorders and considered to be in a preleukemic state. The results were compared with those of two other studies and with the findings for two groups of newborns ($n = 500$ and 800 , respectively). There was a statistically significant increase in the incidence of the major heterochromatic variants, ie, A_1 and C_2 , in the 120 patients compared with the four control groups. Although most of the patients were untreated at the time of examination, an increased chromosome breakage rate was a frequent finding, and it was almost always connected with the presence of heterochromatic variants. A genetically increased susceptibility to breaking agents may explain the increased incidence of heterochromatic variants found in patients with malignant or premalignant diseases. Chromosome imbalance is probably the basis for initiation of malignancy, whose development is influenced by many different factors. (25 refs)

- 79-1695 Occurrence and Significance of Chromosome Aberrations in Malignant Cells (Meeting Abstract).** (Eng) Levan, G. (Dept. Genetics, Univ. Gothenburg, Gothenburg, Sweden). *Heredity (Lond)* 41(part 3): 416; 1978. (no refs)

- 79-1696 K562--A Human Erythroleukemic Cell Line.** (Eng) Andersson, L. C. (Transplantation Lab., Univ. Helsinki, Helsinki, Finland); Nilsson, K.; Gahrberg, C. G. *Int J Cancer* 23(2): 143-147; 1979.

The surface membrane properties of the Philadelphia chromosome-positive human leukemic cell line K562, derived from a patient with chronic myeloid leukemia (CML) in acute blast crisis, were studied. Samples of surface-labeled (using the galactose oxidase- NaB^{14}H , method) normal RBC, K562 cells, HL-60 myeloid cells, normal granulocytes, and cells from patients with CML and acute promyelocytic leukemia were run in parallel slots on the same slab gel. The glycoprotein pattern of K562 showed striking similarities with that of the RBC, but it was completely different from the patterns of the other cells. Gp42 was strongly expressed on K562 cells, and it corresponded in electrophoretic mobility to the monomer of glycophorin (GPN). K562 cells incubated in the cold with the F(ab), preparation of the anti-GPN antiserum and fluorescein isothiocyanate-conjugated

sheep anti-rabbit Ig anti-serum showed a strong membrane fluorescence, as did normal RBC. After incubation of stained cells for 30 min at 37 C, a partial redistribution of the label was seen in some cells, indicating that the anti-GPN antiserum reacts with integral membrane protein(s) of K562 cells. Expression of GPN on the surface of K562 cells was also shown by immunoprecipitation from labeled membrane preparations. Since GPN is exclusively found on erythroid cells in human bone marrow, it is concluded that K562 is a human erythroleukemic line. The observed erythroid features of K562 suggest that, during blast crisis, the neoplastic stem cell has the potential to differentiate not only to immature myeloid or lymphoid cells, but also to erythroid cells. (28 refs.)

- 79-1697 B Cell Acute Lymphoblastic Leukemia (ALL) with a 14q+ Chromosome Abnormality.** (Eng) Roth, D. G. (Univ. Chicago Hosps., Box 420, 950 E. 59th St., Chicago, IL, 60637); Cimino, M. C.; Variakojis, D.; Golomb, H. M.; Rowley, J. D. *Blood* 53(2): 235-243; 1979.

The case report of a 33-yr-old man with acute lymphoblastic leukemia (ALL) associated with the 14q+ marker chromosome is presented. The abnormality resulted from a translocation of material from the long arm of chromosome 11: t(11;14)(q23;q32). The circulating leukemic cells had surface immunoglobulin, a lack of receptors for sheep RBC, and a low level of adenosine deaminase activity, characteristic of B cells. The finding of the 14q+ chromosome is of particular interest because this marker has been reported in only one other case of ALL, which was also a B-cell type. These are the only two cases of B-cell ALL known in which karyotype studies were done with banding techniques. The karyotype in the previous case, although less complex, had other features in common with the present case: an additional No. 7, a loss of No. 13, and a 6p+ rearrangement. The frequent occurrence of the 14q+ chromosome in other malignant lymphoproliferative diseases of B-cell origin suggests that this abnormality may be associated with B-cell neoplasms. The data show the value of cytogenetic studies in identifying discrete variants of hematologic diseases and in relating specific cytogenetic abnormalities with particular syndromes. (25 refs)

- 79-1698 Acute Myeloblastic Leukemia and Non-Hodgkin Lymphoma (Letter to Editor).** (Eng) Lonnqvist, B. (Medicinkliniken, Karolinska Institutet, 141 86 Hud-dinge, Sweden); Lockner, D. *N Engl J Med* 300(7): 367-368; 1979.

The case of a 67-yr-old man who simultaneously presented with a lymphocytic-lymphoblastic retroperitoneal lymphoma and an acute myeloblastic leukemia with Auer rods is reported. The patient had never received x-ray treatment or cytostatic therapy. (15 refs)

- 79-1699 Acute Myelogenous Leukaemia Occurring at the Same Time in Husband and Wife.** (Eng) Ly,

B. (Medical Dept. A, Rikshospitalet, Oslo, Norway); Stavem, P.; Saltvedt, E. *Scand J Haematol* 21(5): 376-378; 1978.

Acute myelogenous leukemia (AML) was diagnosed within 1 wk in a married Norwegian couple (husband aged 40, wife aged 31) without consanguinity. The husband had acute myelomonocytic leukemia, the wife classical-type AML. The husband, a previously healthy salesman, had swollen gums with recurrent and painful ulcerations for 1 yr prior to diagnosis. Three years prior to diagnosis, the wife had complained of pain and stiffness in several joints, symptoms that gradually subsided without treatment. Their histories revealed no cases of malignant blood disorders in their families and no exposure to x-rays, alkylating agents, or benzene and its derivatives. They lived in their own house in a small rural community, and their two children were in good health. In Norway, the probability for a married couple to develop AML within the same year is approx 1:400 million. If a common etiological factor had been involved, it certainly led to quite a different morphologic expression. (7 refs)

79-1700 Inbreeding, Lymphoma, Genetics and Morphology of the *Papio hamadryas* Colony of Sukhumi. (Eng) Crawford, M. H. (Lab. Biological Anthropology, Univ. Kansas, Lawrence, KS, 66044); O'Rourke, D. H. *J Med Primatol* 7(6): 355-360; 1978.

A preliminary report of visits to the Sukhumi Primate Center, USSR, which houses a colony of *Papio hamadryas* baboons that are infected with human lymphoma, is given. Examination of the pedigrees of the hamadryas population indicated that inbred baboons were at greater risk of contracting lymphoma than animals captured in the wild and that the disease was concentrated in certain lineages. Blood samples, morphological data, and complete pedigrees are being analyzed to explore the interactions between genetic and environmental factors in the etiology of lymphoma. (12 refs)

79-1701 Post-Capillary Venules in the Lymphatic Tissues of Mice Bearing Experimental Neoplasia. (Eng) Syrjanen, K. J. (Dept. Pathology, Jorvi Hosp., SF-02740 Espoo 74, Finland). *Exp Pathol (Jena)* 15(6): 348-354; 1978.

Light microscopy was used to study morphologic changes in the postcapillary venules (PCV's) of the lymph nodes, thymus, and Peyer's patches of normal DBA/2 mice and mice bearing mastocytomas. Some of the mice were treated sc with anti- θ -globulin prior to tumor cell inoculation. Three classes of PCV's were differentiated according to the height of the endothelial cells of the vessels. The highest mean PCV scores for lymph nodes and Peyer's patches were observed in normal mice, the scores in tumor-bearing mice being significantly lower. The scores of the tumor-bearing mice did not differ significantly from those of the tumor-bearers pretreated with anti- θ -globulin. PCV scores of the thymuses were low and did not differ significantly between normal and

tumor-bearing mice. Thus, a direct correlation seems to exist between the degree of T-cell depletion and the morphology of the PCV's in lymph nodes and Peyer's patches. The data support the concept that the structural state of the PCV endothelium is an important regulator of T-lymphocyte recirculation in nodes and Peyer's patches. (21 refs)

79-1702 Ultrastructural Organization of Thrombocytes in Normal Monkeys (*Macaca arctoides*) and in Those with Experimental Viral Malignant Lymphoma. (Eng) Chuvirov, G. N. (Institute Experimental Pathology and Therapy, USSR Acad. Medical Sciences, Gora Trapetziya, P.B. 66, Sukhumi, USSR); Fomenko, V. N. *Exp Pathol (Jena)* 15(6): 319-323; 1978.

The ultrastructure of the thrombocytes of healthy *Macaca arctoides* monkeys and monkeys with viral malignant lymphoma induced by inoculation with leukemic human blood was compared. The inner structure of the thrombocytes from the healthy monkeys was similar to that of normal human thrombocytes. The first ultrastructural changes in the thrombocytes for the lymphoma-bearing monkeys appeared 20 days after inoculation, almost simultaneously with the appearance of the first clinical symptoms. By the 60th day, elongated platelet forms were reduced to 80%-85% of the initial number and there was a 15%-20% increase in the number of gigantic roundish thrombocyte forms. The number of alpha, beta, and sigma granules was decreased, whereas the number of glycogen granules was increased. The size of the delta granules also increased. These changes may have resulted from the effects of the leukemic process on cell function and on the bone marrow megakaryocytes. Viral particles were not found in the thrombocytes of any sick monkey. (22 refs)

79-1703 Trisomy #15 in Murine Thymomas Induced by Chemical Carcinogens, X-Irradiation, and an Endogenous Murine Leukemia Virus. (Eng) Chan, F. P. (Dept. Anatomy, Univ. Western Ontario, London, Ontario, Canada N6A 5B7); Ball, J. K.; Sergovich, F. R. *J Natl Cancer Inst* 62(3): 605-610; 1979.

Chromosome banding techniques were used to examine the karyotype of tumor cells from thymic lymphomas induced in two low-leukemia mouse strains (CFW/D and C57Bl/Ka) (x-irradiation, polycyclic aromatic hydrocarbons, and an endogenous leukemogenic virus). Treatment consisted of 400 rads of x-radiation, injection of 40 μ 7,12-dimethylbenz(a)anthracene (DMBA) or 150 μ g benzo(a)pyrene, or injection of a DMBA-induced leukemia virus into a newborn mouse thymus placed under the kidney capsule of a normal 6-wk-old adult mouse. A total of 89 tumors were studied, and of these 85.4% were characterized by a modal chromosome number of 41. The additional chromosome was the result of a specific abnormality identified as trisomy of chromosome 15. The results were independent of the carcinogenic agents and the strain of mouse used. Of the 13 tumors found to have a normal chromosome complement, 4 were induced by x-irradiation.

tion and the remaining 9 by the chemical carcinogens. All 15 virus-induced tumors analyzed had a modal chromosome number of 41. (26 refs)

- 79-1704 Sarcoma Arising in Oligodendroglioma of the Brain: A Case with Intramedullary and Subarachnoid Spinal Metastases.** (Eng) Pasquier, B. (Dept. Pathology, CHU de Grenoble, B.P. 217 X 38043, Grenoble Cedex, France); Couderc, P.; Pasquier, D.; Panh, M. H.; N'Golet, A. *Cancer* 42(6): 2753-2758; 1978.

The case of a 39-yr-old man with a sarcoma arising in a left temporal oligodendroglioma is presented. Postoperatively, the patient became paraplegic because of subarachnoid metastases. The results of myelography and surgical findings strongly suggested that this metastasis was associated with an intramedullary localization. Histologically, the sarcomatous component of the tumor was both fibrosarcomatous and angiosarcomatous. The patient died following a recurrence of the cerebral tumor. The histological findings support previously reported hypotheses that sarcoma develops from the neoplastic transformation of vascular wall elements or is of endothelial origin. (25 refs)

- 79-1705 Ultrastructure of Malignant Schwannomas (Meeting Abstract).** (Eng) Chiu, H. F. (Dept. Pathology, Victoria Hosp., London, Ontario, Canada N6A 4G5); Troster, M. *Lab Invest* 40(2): 246; 1979. (no refs)

- 79-1706 Cardiac Myxoma: Biochemical Analyses and Evidence for Its Neoplastic Nature.** (Eng) Bashy, R. I. (Dept. Medicine--Rheumatology, Sch. Medicine, Univ. Pennsylvania, 536 Johnson Pavilion, 36th and Hamilton Walk, Philadelphia, PA, 19104); Nochumson, S. *NY State J Med* 79(1): 29-32; 1979.

Biochemical characterization of the ground substance from two cardiac myxomas revealed that both lesions contained approx 3 mg of hexosamine-containing macromolecules per 100 mg dry fat-free tissue, out of which about 66% was glycosaminoglycans. The absence of dermatan sulfate and the high proportion (>75% of total glycosaminoglycans) of chondroitin 4 and/or 6 sulfates suggest that cardiac myxomas are neoplastic in nature. (18 refs)

- 79-1707 Pulmonary Hypertension Caused by Neoplastic Thrombosis of the Pulmonary Artery.** (Fre) Beaufils, P. (Hopital Lariboisiere, 2 rue Ambroise-Pare, 75475 Paris Cedex 10, France); Cywiner-Golenz, C.; Perault, M. A.; Rymer, R.; Slama, R. *Arch Mal Coeur* 71(7): 816-822; 1978.

Neoplastic thrombosis of the pulmonary artery is a rare cause of pulmonary hypertension that can only be distinguished at autopsy from subacute cor pulmonale due to embolism. Two

cases are reported, one in a 51-yr-old man and one in a 41-yr-old woman, and the principal clinical and pathological characteristics are reviewed. The man entered the hospital with cyanosis, dyspnea, and an unproductive cough. Pulmonary auscultation was normal. The liver was enlarged with hepatojugular reflux. Angiography revealed dilation of the main pulmonary artery and two branches and narrowing or obliteration of the pulmonary arterioles. A right ventricular surcharge was observed on the electrocardiogram (EKG). The patient died within a month, and autopsy revealed neoplastic thrombosis of the distal arterioles of the lung. Diagnosis was carcinomatous lymphangitis with secondary invasion of arterioles. The woman was hospitalized with dyspnea, edema of the lower limbs, and cardiac irregularities. X-rays of the thorax showed a slightly enlarged heart and normal pulmonary arteries. A right branch block was noted on the EKG. Angiography confirmed massive thrombosis with obliteration of the left pulmonary field. The patient died shortly after hospitalization. Histological examination of the lung at autopsy revealed numerous white emboli obstructing the lung arterioles and a large fibrinous thrombus obstructing almost the entire right ventricular cavity. The cells composing the emboli were typical of a choriocarcinoma; however, the primary tumor was not found. (6 refs)

- 79-1708 Combined Cytological-Histological Examination of Bone Marrow. Experience with 200 Patients.** (Fre) Delacretaz, F. (Institut de pathologie, CHUV, CH-1011 Lausanne, Switzerland); Schmidt, P. M. *Schweiz Med Wochenschr* 109(1): 13-18; 1979.

The combination of bone marrow aspiration and bone marrow biopsy was evaluated in 200 patients with malignant lymphoma (53), multiple myeloma (49), myeloproliferative syndromes (35), metastases (15), and other hematological disorders (cytopenia, anemia, leukemia: 48). In 152 of the patients, the two methods were equivalent. Nevertheless, a comparison of the cytological and histological techniques provided greater diagnostic confidence. In 24 patients, the bone marrow biopsy was the only diagnostic procedure used. Bone marrow aspiration proved superior in the remaining 24 patients, as it was better able to detect small and discrete malignant infiltrates and it gave a more detailed analysis of blasts and cytological changes in cell maturation. On the basis of the results with this series of 200 patients, it is concluded that a combination of the two methods appears indispensable for evaluating lympho- and myeloproliferative syndromes, cytopenias with or without fever of unknown origin, and metastatic disease. (29 refs)

- 79-1709 Chondrosarcoma of the Hand.** (Eng) Trias, A. (Dept. Orthopaedic Surgery, Univ. Sherbrooke Sch. Medicine, Sherbrooke, Quebec, Canada); Basora, J.; Sanchez, G.; Madarnas, P. *Clin Orthop* (134): 297-301; 1978.

A case of chondrosarcoma of the hand that recurred four times over a period of 32 yr is presented. The patient was first

seen, at the age of 37, with an enchondroma of the second metacarpal; this was curetted and bone grafted. Chondrosarcoma at the site was first diagnosed 9 yr later, the time of the first recurrence. The involved finger was amputated, but the tumor recurred three additional times on the third metacarpal. Tumor spread eventually resulted in amputation at the wrist. The lesion may have been a chondrosarcoma in the beginning, or malignant transformation of benign cartilaginous seedlings left during the first surgery may have occurred. (16 refs)

- 79-1710 Chondrosarcoma of the Talus. A Case Report.** (Eng) DeBenedetti, M. J. (Dept. Orthopaedic Surgery, New York Univ. Medical Center, 550 First Ave., New York, NY, 10016); Waugh, T. R.; Evanski, P. M.; Jordan, I.; Krijger, M. *Clin Orthop* (136): 234-237; 1978.

The unusual case of a 27-yr-old man who developed chondrosarcoma of the talus following ankle trauma is presented. The condition was misdiagnosed as ankle sprain or Sudek's atrophy by seven physicians. The correct histological diagnosis was made after radiographs showed a large soft tissue mass, soft tissue calcification, and progressive destruction of the posterior aspect of the talus. (16 refs)

- 79-1711 A Sixth Complementation Group in Xeroderma Pigmentosum.** (Eng) Arase, S. (Dept. Dermatology, Tokushima Univ. Sch. Medicine, Tokushima 770, Japan); Kozuka, T.; Tanaka, K.; Ikenaga, M.; Takebe, H. *Mutat Res* 59(1): 143-146; 1979.

A sixth complementation group was discovered in the fibroblast cells of a 45-yr-old woman with a mild case of xeroderma pigmentosum. These cells showed only 10% of the normal level of unscheduled DNA synthesis at 30 joules/m² of UV exposure. However, there was an intermediate level of DNA repair. (7 refs)

- 79-1712 Fibrous Epulis: Experience in Clinical Presentation and Treatment of 39 Cases.** (Eng) Ajagbe, H. A. (Dept. Dentistry, Univ. Coll. Hosp., Ibadan, Nigeria); Daramola, J. O. *J Natl Med Assoc* 70(5): 317-319; 1978.

The clinical features of 39 cases of fibrous epulis that occurred over a 5-yr-period are described. Thirty patients were women, 20 of whom were 21-40 yr old. Eleven were pregnant at presentation. Many epulides attained giant sizes before patients sought treatment, and they interfered with speech or mastication. In a few cases, giant cells were scattered in the lesions. No malignant cells were found in any cases. The tumor recurred in only 2/38 patients in whom the lesion was excised. A few large or recurrent fibrous epulides were mistaken for malignant lesions. - 79-1715 Lung Colony Formation: A Selective Cloning Process for Lung-Colony-Forming Ability.** (Eng) Suzuki, N. (Section Experimental Radiotherapy, Univ. Texas System Cancer Center, M. D. Anderson Hosp. Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030); Withers, H. R. *Br J Cancer* 39(2): 196-199; 1979.

The lung-colony-forming efficiency (LCFE) of cells cultured from secondary lung nodules (LC1) of mice was compared with that of cells cultured from sc mouse tumors (T1) and from the original mouse fibrosarcoma cells (FSA 1233). Single cell suspensions of 10⁴-10⁵ cells in 0.5 ml of medium were injected into tail veins of unirradiated C3Hf/Bu mice. LC1 cells had a higher LCFE than the original FSA 1233 cells, whereas the T1 cells showed an LCFE similar to that of the original FSA 1233 cells. In additional experiments using other inoculation routes, there was no difference in survival time of mice inoculated sc with lung nodule cells and those inoculated sc with FSA 1233 cells, despite the 10-fold greater artificial LCFE of the former. The data showed that the selection of increased metastatic efficiency was specific to the organ in which the metastases were passaged. (19 refs)

- 79-1716 Adenocarcinoma of the Lung: Pericardial Tamponade as the Major Presenting Feature.** (Eng) Damuth, T. E. (Dept. Medicine-Chest, Univ. Michigan Coll. Medicine, Ann Arbor, MI); Bush, C. A.; Leier, C. V. *Ohio State Med J* 75(1): 25-27; 1979.

The cases of three patients with bronchogenic adenocarcinoma presenting as pericardial tamponade are reported, and two previously reported cases are reviewed. None of the five patients manifested symptoms usually associated with primary pulmonary malignancy. No discrete mass lesions were revealed on the initial chest roentgenograms. Pericardial biopsy and pericardial and pleural fluid cytologic studies gave a high diagnostic yield. (6 refs)

- 79-1717 Fiber Endoscopy and Radiology for Gastric Ulcer, Gastric Carcinoma, and Hiatal Hernia.** (Ger) Killer-Walser, R. (Medizinische Klinik, Stadtspital Triemli, CH-8063, Zurich, Switzerland); Hess, H.; Wursch,

T. G.; Stuby, K.; Sonnenberg, A.; Bruhlmann, W.; Blum, A. L. *Schweiz Med Wochenschr* 109(1): 3-6; 1979.

Between 1973 and 1976, 306 patients underwent both fiber endoscopy and radiology examination within a 7 day period. Radiology was performed before endoscopy in 196 patients and after endoscopy in 110 patients. Follow-up studies were made of patients with histologically unproved divergent findings. In the diagnosis of gastric ulcer and gastric cancer, endoscopy with biopsy was more accurate than radiology. In the diagnosis of hiatal hernia, radiology was more accurate. Significant additional findings that were difficult or impossible to observe with endoscopy were revealed in 36% of the radiological examinations. These secondary findings included pathological gastroesophageal reflux in 55 patients, pathological tertiary esophageal contractions in 30, gastric retention in 22, carcinoma of the head of the pancreas in 4, cholelithiasis in 4, cholecystoduodenal fistula in 2, and splenomegaly in 1. Thus, endoscopy should be performed first when gastric ulcers or carcinoma is suspected. Radiology should be performed first in patients with uncharacteristic epigastric symptoms. (13 refs)

79-1718 Necessity of Gastroscopy in the Immediate Follow-up of Sutured Perforated Gastric Ulcer.

(Fre) Claudel, S. (Centre d'Endoscopie Digestive, Hôpital Edouard-Herriot, place d'Arsonval, F 69374 Lyon Cedex 2, France); Lambert, R.; Moulinier, B.; Gruffaz, B. J. *Nouv Presse Med* 7(46): 4234; 1978.

Three patients underwent surgery for perforated gastric ulcer without preceding gastroscopy or biopsy. Gastric cancer was diagnosed by intraoperative biopsy in one patient and by gastroscopy because of recurrent pains several years' postsurgery in the others. (4 refs)

79-1719 Carcinoma of the Small Intestine in Regional Enteritis. Presentation of a Case and Review of the Literature. (Eng) Floch, H. F. (Dept. Surgery, New York Univ. Coll. Medicine, New York, NY); Slaterry, L. R.; Hazzi, C. G. *Am J Gastroenterol* 70(5): 520-527; 1978.

The case of a 53-yr-old man with a 32-yr history of Crohn's disease (regional enteritis) who developed jejunal carcinoma is presented. Forty-seven previously reported small bowel carcinomas in Crohn's disease patients are reviewed. Incidence statistics and pathological features of the Crohn's carcinomas and de novo small bowel carcinomas are compared. (45 refs)

79-1720 In Vivo and In Vitro Studies of the Metastatic Process (Meeting Abstract). (Eng) Dollbaum, C. M. (Univ. California, Berkeley, CA). *Diss Abstr Int B* 39(8): 3695; 1979. (no refs)

79-1721 Precancerous Lesions of the Colon and Rectum. (Eng) Gotoh, A. (First Dept. Surgery, Gifu Univ. Medical Sch., Gifu City, Japan); Iwashima, Y. *Jpn J Surg* 8(4): 315-325; 1978.

The relationship between adenomatous polyps and the development of cancer of the colon and rectum was investigated in 46 cases of polyps and polypoid lesions of the colon and rectum operated at a Japanese hospital over the last 16 yr. The lesions were classified into three groups: adenomatous and malignant polyps (30 cases), villous tumor (1), polypoid cancer (15). In addition, the polyps were classified into five groups according to their degree of atypia. Adenomatous polyps tended to become malignant. It appeared that the larger the polyp size, the greater the incidence of severe atypia and the greater the malignant potential. Malignant polyps developed more frequently in the distal colon and rectum than in other parts. Focal and invasive cancers limited to the submucosal layer were found exclusively in the sigmoid colon and rectum. (10 refs)

79-1722 Atypical Appendiceal Carcinoid. (Eng) Stillman, R. M. (Dept. Surgery, State Univ. New York Downstate Medical Center, 450 Clarkson Ave., Brooklyn, NY, 11203); Alfonso, A.; Nicastrì, A.; Gardner, B. *NY State J Med* 79(1): 98-100; 1979.

An unusual case of appendiceal carcinoid is reported. The patient, a 27-yr-old woman, presented with right lower quadrant pain and an abdominal mass. At laparotomy, an indurated mass extending into the cecum and terminal ileum was palpated at the base of the inflamed, distended appendix. The proximal location and cecal extension of the lesion prevented simple appendectomy, and segmental resection was performed. The tumor obstructed the appendiceal lumen, extended through the muscularis into the serosal fat, and was metastatic to one adjacent lymph node. (no refs)

79-1723 The Induction of Cystitis and the Implantation of Tumours in Rat and Rabbit Bladders. (Eng) Edwards, L. (Dept. Urology, Westminster Hosp., Horseferry Road, London SW1, England); Rosin, D.; Leaper, D.; Swedan, M.; Trott, P.; Vertido, R. *Br J Urol* 50(7): 502-504; 1978.

Cystitis was induced and tumors implanted in the bladders of female Sprague-Dawley rats and female New Zealand White rabbits. The animals were anesthetized and their bladders emptied and then filled with the chemical irritant Cetavlon (CTV). CTV was left in the bladder for 30 min. Four animals of each species were sacrificed at this stage (acute experiments). In the remaining animals (6 rabbits, 10 rats), CTV was withdrawn and the bladder was filled with a suspension of Walker sarcoma (rats) or Vx2 sarcoma (rabbits). Animals were allowed to recover and then sacrificed at 7 days. In acute experiments, the normal transitional cell lining of the bladder underwent considerable change in all animals. The epithelium was hyperemic and often lifted away from the

submucosa by edema fluid. There was patchy detachment of clumps of cells, leaving the submucosal layer bare, and considerable submucosal vascular congestion and hemorrhage. In the implantation experiments, all three surviving rabbits and six surviving rats had bladder tumors. In the former, the plaques were small and mainly subepithelial; in the latter, the size of the tumor varied from small plaques to a mass almost filling the bladder. Tumor was also found in one of both kidneys in 3/6 rats. The results show that it is relatively simple to produce tumor growth in animal bladders, but only if cystitis has been induced with an irritant chemical. At the same time, if reflux occurs, it is also possible to induce tumor growth in the kidney. CTV, which is occasionally used as an antiseptic for bladder irrigations, rapidly induced a severe cystitis. The presence of infections, chemical or bacterial, may be significant in patients with recurrent bladder tumor. (4 refs)

- 79-1724 Comparative Electron-Microscopic Studies of Benign Hepatoma and Icterus in Patients on Oral Contraceptives.** (Eng) Balazs, M. (Dept. Pathology, Janos Hosp. Budapest Council, Diosarok ut 1, 1125 Budapest, Hungary). *Virchows Arch [Pathol Anat]* 381(1): 97-109; 1978.

The ultrastructure of six benign liver tumors (1 liver cell adenoma and 5 cases of focal nodular hyperplasias) and three specimens of icteric liver tissue, all from women on oral contraceptives, was compared. Most of the changes were identical in both the tumor and icteric cases. The lumen of the bile canaliculi was usually dilated by an accumulation of a filamentous substance, and the microvilli in the canaliculi were destroyed. The mitochondria, which varied greatly in size and shape, contained a large number of paracrystalline inclusions; in some cases, the external double membrane was missing. On the sinusoidal cell surface, edema of the microvilli and herniation of the cytoplasm were observed. There was an accumulation of a granular, filamentous substance in Disse's space. In some places, the plasma membrane was missing. The sinusoidal endothelial cells were hyperplastic, with increased protein production. Formation of a basement membrane was seen all around the endothelial cells. The only important difference detected between the tumor and icteric liver tissue was the formation of continuous capillaries at the site of the sinusoids in the tumor tissue. (40 refs)

- 79-1725 Liver Ultrasonography in Multinodular Hemangioendothelioma (Case Report).** (Ger) Frank, T. (Klinik für Nuklearmedizin und Radiotherapie, Stadtspital Triemli, Birmensdorfer Strasse 497, CH-8063 Zurich, Switzerland); Rampini, S. *ROEFO* 129(6): 791-793; 1978.

Liver sonography was decisive in the diagnosis of multinodular hemangioendotheliomas in a 3.5-mo-old boy. After prednisone treatment, a repeat sonography at age 13 mo showed marked regression of the tumor. The use of liver sonography

in diagnosing hemangioendotheliomas has not been reported previously. (5 refs)

- 79-1726 Differences in Cell Surface Antigens of Tumor Metastases and Those of the Local Tumor.** (Eng) Fogel, M. (Dept. Cell Biology, Weizmann Inst. Science, Rehovot, Israel); Gorelik, E.; Segal, S.; Feldman, M. *J Natl Cancer Inst* 62(3): 585-588; 1979.

Tests were made to determine whether cell surface tumor antigens of metastases differed from those of the local tumor. C57BL/6 mouse spleen lymphocytes sensitized against monolayers of a local growth of 3LL Lewis lung carcinoma (L-3LL) in the presence of syngeneic serum generated lymphocytes that were cytotoxic to L-3LL but significantly less cytotoxic to target cells derived from lung metastases (M-3LL). Lymphocytes sensitized against M-3LL were significantly more cytotoxic against M-3LL than against L-3LL cells. Anti-M-3LL cytotoxic lymphocytes, but not anti-L-3LL lymphocytes, admixed with either L-3LL cells or M-3LL tumor cells reduced lung metastasis significantly when injected into syngeneic recipients. The results indicate that cells with high metastatic capacity and distinct antigenic properties exist within the tumor cell population and that immunoselection might be involved in the production of lung metastases. (16 refs)

- 79-1727 The Role of Genetic Factors in the Etiology of Wilms' Tumor. Two Pairs of Monozygous Twins with Congenital Abnormalities (Aniridia; Hemihypertrophy) and Discordance for Wilms' Tumor.** (Eng) Maurer, H. S. (Dept. Pediatrics, Northwestern Univ. Medical Sch., Children's Memorial Hosp., 2300 Children's Plaza, Chicago, IL, 60614); Pendergrass, T. W.; Borges, W.; Honig, G. R. *Cancer* 43(1): 205-208; 1979.

Wilms' tumor was diagnosed in two children, each with an identical twin. In one of the pairs the aniridia syndrome with psychomotor retardation was present in both children, but Wilms' tumor was found in only one. In the other pair hemihypertrophy as well as Wilms' tumor were identified in one child, but neither of these abnormalities was present in her twin sister. These findings support the hypothesis that the development of Wilms' tumor requires the occurrence of two successive mutational events, one of which may be a germinal mutation. The presence of aniridia, hemihypertrophy, or other associated congenital abnormalities may aid in distinguishing between hereditary and sporadic forms of Wilms' tumor. (21 refs)

- 79-1728 Intrarenal Neuroblastoma Mimicking Wilms' Tumor.** (Eng) Shende, A. (Div. Pediatric Hematology-Oncology, Long Island Jewish-Hillside Medical Center, New Hyde Park, NY); Wind, E. S.; Lanzkowsky, P. *NY State J Med* 79(1): 93; 1979.

The case of a 13-mo-old boy with neuroblastoma arising in an intrarenal location and presenting the classic radiographic features of Wilms' tumor is reported. (2 refs)

- 79-1729 Carcinoid Tumor of the Kidney. Report of a Case.** (Fre) Lanson, Y. (Service d'Urologie, C.H.U. Bretonneau, 37000 Tours, France); Bruant, D.; Benatre, A.; Rivalan, P.; Brizon, J. *J Urol Nephrol (Paris)* 84(1/2): 47-51; 1978.

A carcinoid tumor of the kidney was diagnosed in a 65-yr-old man who entered the hospital with a fever that had persisted for several weeks, despite antibiotic therapy. A large, painful mass palpated in the lumbar region and an *Escherichia coli* pyuria led to the diagnosis of pyonephrosis of a horseshoe kidney. At surgery, pyonephrosis and stenosis of the renal calix junction were observed, and the right half of the horseshoe kidney was excised. A carcinoid tumor 2 cm in diameter was found upon histological examination of the specimen. Dysgenetic cellular elements were observed in the region of the tumor. Complete evaluation of the patient failed to reveal a tumor at any other site. It was concluded that the kidney carcinoid tumor resulted from a neoplastic change in a dysplastic zone of the kidney. Carcinoid tumors of the kidney support the hypothesis that the renal blastema is derived not only from the mesenchyme but also from the neural crests, since cells from the crest have the potential of differentiating into cells of the diffuse endocrine system. - 79-1730 Urothelial Tumors in Essential Fatty Acid Deficient Rats (Meeting Abstract).** (Eng) Monis, B. (Instituto de Biologia Celular, Universidad Nacional de Cordoba, Casilla Postal 220, 5.000 Cordoba, Argentina); Eynard, A. R. *Fed Proc* 38(3, part 2): 1451; 1979. (no refs)

- 79-1731 The Appearance of Tumor Cells in the Milk of C3H Mice in Successive Pregnancies (Meeting Abstract).** (Eng) Miller-Catchpole, R. (Dept. of Pathology, Univ. Illinois at the Medical Center, Chicago, IL); McGrew, E. A.; Catchpole, H. R. *Anat Rec* 193(3): 625; 1979. (no refs)

- 79-1732 Isolated Adenocarcinomatous Transformation in Uterine Adenomyosis.** (Fre) Baril, A. (Service d'Anatomie Pathologique, CHU Bellevue, boulevard Pasteur, 42023 Saint-Etienne Cedex, France); Boucheron, S.; la Selve, A. *Arch Anat Cytol Pathol (Paris)* 26(3/4): 177-180; 1978.

Adenomyoma was tentatively diagnosed in a 48-yr-old nullipara who initially refused to undergo surgery. Consent was given 4 yr later, and subtotal hysterectomy with adnexectomy was performed. Histological examination of the resected tissues revealed polyfibromyomatosis with subserous and interstitial myomas. The fibromyomas were infiltrated by an en-

dometrial adenocarcinoma. Several foci of adenomyosis were seen in the uterine wall. (31 refs)

- 79-1733 Behavior of Cervical Epithelium During Carcinogenesis: Autoradiography of Tritiated Cytidine in the C57BL Mouse.** (Eng) Rubio, C. A. (Inst. Pathology, Karolinska Sjukhuset, S-104 01 Stockholm 60, Sweden). *J Natl Cancer Inst* 62(3): 629-631; 1979.

An investigation was made of the autoradiographic patterns of the cervical epithelia of 39 virgin C57BL mice after in vivo injection of ³H-cytidine. Of the 22 animals whose cervixes were painted 2x/wk with 1% benzo(a)pyrene soln for 5 mo, 8 developed intraepithelial atypias and 2 had invasive carcinoma. The mean number of silver grains in individual cells increased from histologically normal cervical epithelium through atypical epithelium to invasive carcinoma. The autoradiographic patterns in normal, atypical, and invasive carcinoma cells apparently reflected quantitative differences in normal, atypical, cytidine incorporation. These differences may denote an increased demand for RNA precursors in the cervical epithelium during carcinogenesis. (9 refs)

- 79-1734 Extramammary Paget's Disease.** (Eng) Breen, J. L. (St. Barnabas Medical Center, Livingston, NJ); Smith, C. I.; Gregori, C. A. *Clin Obstet Gynecol* 21(4): 1107-1115; 1978.

A histopathologic and clinical evaluation of 13 patients with vulvar Paget's disease seen during 1970-1977 is presented, and reports on the disease published in the past 20 yr are reviewed. Vulvar Paget's disease is a rare disease of postmenopausal women primarily in the sixth and seventh decades, and it involves the skin and its appendages in a multifocal fashion. It is commonly manifested by vulvar pruritus, irritation, or a burning sensation, and it usually appears as a well-defined, moist, reddish lesion involving the labia and occasionally extending over the entire vulva and peritoneum. It is present as an in situ lesion for a long time before it invades the dermis. Five of the 13 patients and 25/85 from the literature had an associated or prior malignancy. Including 7 patients with breast cancer, a total of 16 of these malignancies were related to the genital tract. Although the recurrence rates were similar at different levels of histologic involvement, the death rates of 0% and 8.3% with epidermal and glandular involvement, respectively, increased to 50% when invasion of the dermis was present. Theories for the origin of this disease fall into three basic categories: (1) origin from an underlying ductal or glandular carcinoma; (2) an intraepithelial origin with subsequent sweat gland and dermal involvement; and (3) a multifocal origin. (21 refs)

- 79-1735 Diseases of the Vulva Presenting as White Lesions.** (Eng) Young, A. W. (St. Luke's Hosp. Center, New York, NY); Tovell, H. M. *Clin Obstet Gynecol* 21(4): 1023-1039; 1978.

The various diagnoses of white lesions of the vulva and their incidence in 484 patients who attended a cutaneous-vulva clinic during 1971-1977 are reported. The 14 different conditions diagnosed were divided into two clinically distinguishable groups: (1) those in which leukoderma was invariably present and persisted throughout the course of the disease; and (2) those in which leukoderma was a complicating feature of an active or resolving inflammatory process or became apparent as a result of increased moisture superimposed on hyperkeratosis. The first group included 77 cases of vulvar dystrophy [lichen sclerosus (68), hyperplastic dystrophy (4), lichen planus (1), and mixed dystrophy (4)] and 22 cases of vitiligo. The second group included scar (2), candidiasis (148), lichen simplex chronicus (81), intertrigo (29), psoriasis (12), condyloma latum (4), verruca genitalis (88), intraepithelial neoplasms (7), and postinflammation lesions (14). None of the 77 vulvar dystrophy patients evidenced neoplasia during the observation period. The carcinoma in situ seen in seven patients frequently showed whiteness because of hydration of the dyskeratotic horny layer. It is concluded that only an extremely small percentage of patients in the population served by the clinic who presented with a white or potentially white lesion of the vulva had an active neoplastic or preneoplastic process. (17 refs)

- 79-1736 Classification of Vulvar Diseases.** (Eng) Tovell, H. M. (St. Luke's Hosp. Center, New York, NY); Young, A. W. *Clin Obstet Gynecol* 21(4): 955-961; 1978.

The operation of a cutaneous-vulvar clinic is described, and a simple classification of vulvar diseases and the frequency with which they were encountered at the clinic are presented. In the first 1,000 consecutive patients, there were 64 different diagnoses. Each condition was classified according to its point of origin into one of three groups: cutaneous-vulvar disorders (CVD, 78%), vulvovaginal disorders (19.4%), and undetermined disorders (2.6%). Neoplasms, including seven carcinomas in situ and four invasive carcinomas, were diagnosed in 198/703 patients with primary CVD. (3 refs)

- 79-1737 Mixed Mesodermal Tumor and Clear Cell Carcinoma Arising in Ovarian Endometriosis.** (Eng) Cooper, P. (Pathology Dept., Level 5, Addenbrooke's Hosp., Hills Road, Cambridge, England). *Cancer* 42(6): 2827-2831; 1978.

A case of clear cell carcinoma and mixed mesodermal tumor arising together in a focus of ovarian endometriosis is presented. The patient, a 53-yr-old woman who was 3 yr postmenopausal, underwent surgery for the removal of a right ovarian cyst. The endometrial cyst contained papillary nodules showing features of clear cell carcinoma. The surface of the largest papillary nodule had a clear cell pattern, but the stroma beneath contained abundant striated muscle. Strap-shaped rhabdomyoblasts were present, and a single

focus of well-formed cartilage was identified in the midst of striated muscle. The epithelial component of the mesodermal tumor consisted of clear cells. The origin of this tumor from within a focus of endometriosis supports the theory that both the epithelial and mesodermal components are of müllerian (paramesonephric) origin. (20 refs)

- 79-1738 Familial Occurrence of Testicular Neoplasms (in Cousins).** (Eng) Madduri, S. D. (Dept. Surgery, New Jersey Medical Sch., Newark, NJ); Gellman, A. C.; Sporer, A.; Seebode, J. J. *Urology* 13(1): 67-69; 1979.

The occurrence of testicular neoplasms in two families is reported. In the first family, two brothers and their second cousin (maternal uncle's daughter's son) were affected, and in the second family, two first cousins were affected. Eighteen reports of a familial occurrence of testicular tumors have appeared in the literature, but this is the first report of these neoplasms occurring in cousins. The occasional familial incidence of the disease, its relative rarity in blacks, and its association with cryptorchism are consistent with a genetic influence, but such an influence has not been established. It is suggested that the other members of the family be checked when a testicular tumor is detected. (21 refs)

EPIDEMIOLOGY AND BIOMETRY

- 79-1739 Mortality Experience of Arsenic-exposed Workers.** (Eng) Pinto, S. S. (ASARCO, Inc., Takoma, WA); Henderson, V.; Enterline, P. E. *Arch Environ Health* 33(6): 325-331; 1978.

The mortality experience of 527 pensioners from a copper smelter who were aged 65 or over between 1949 and 1973 was studied. The av duration of employment was 28 yr, and it ranged from 7 to 54 yr. An index of arsenic exposure was developed for all operations in the plant for 1973. This was applied to all individuals studied, so that a comparative measure could be made of each individual's working-life exposure to arsenic. The overall mortality of this cohort was 12.2% higher than that for men living in the same area, of the same ages, and in the same time periods. The excess mortality was due chiefly to respiratory cancer, for which mortality was three times that expected. This excess was not due to cigarette smoking. Because other contaminants were present in the atmosphere, it is not certain that arsenic was entirely responsible for the respiratory cancer observed, yet a close association with arsenic seems highly likely. (15 refs)

- 79-1740 Study of 201 Workers in an Asbestos Textile Factory.** (Fre) Molina, C (Clinique de Pneumologie, Hopital Sabourin, B.P. 12, La Plaine, 63018 Clermont-Ferrand, France); Cheminat, J. C.; Tourreau, A.; Brun, J.; Maillet, J.; Petit, R.; Gourgand, A. J. *Rev Fr Mal Respir* 6(5): 471-482; 1978.

Among 201 employees in an asbestos textile factory, 34% had x-ray evidence of parenchymal and pleural disorders. Eighty-nine workers had decreased pulmonary function and 25 had decreased overall CO diffusion. There were three cases of cancer (in the lungs, larynx, and stomach, respectively). Correspondence analysis and Fischer's discriminating analysis demonstrated that there was a positive correlation between the degree of pulmonary insufficiency and the amount of dust to which the workers were exposed. At the end of the study, 149 workers were considered to be free of pulmonary disease and 20 were diagnosed with asbestosis. The remaining 32 workers demonstrated either an isolated disorder upon functional examination (including the 3 cancer cases) or asbestos particles in the sputum and were considered a high-risk group, to be kept under strict surveillance. (26 refs)

- 79-1741 Radiation Therapy of the Nasopharynx: A 30 Year View.** (Eng) Loeb, W. J. (2065 Adelbert Road, Cleveland, OH, 44106). *Laryngoscope* 89(1): 16-21; 1979.

The results of a 15- to 30-yr follow-up study of radium therapy to the nasopharynx for serous otitis, Eustachian tube ob-

struction, and conductive deafness are reported, and the relevant literature is reviewed. In the follow-up study, 28/41 patients who had Ra treatment between 1946 and 1961, when it was discontinued, were reexamined in 1976-1977. No tumor or other complication was found. Twenty-four had good results from treatment. The literature cases include about 25,000 treatments reported by the originator of the method, one review of a 27-yr experience, and series of 263, 552, 480, and 2,400 patients. No malignancies were reported in any of these series 15-30 yr after therapy. It is suggested that Ra treatment using the Crowe applicator is still a useful treatment of persistent recalcitrant serous otitis with hearing loss and that it should not have been abandoned because of public pressure and fear of radiation-induced cancer. - 79-1742 Malignant Melanomas in New Mexico: A Model for One Kind of Environmental Pathology Study (Meeting Abstract).** (Eng) Key, C. R. (Univ. New Mexico Sch. Medicine, Albuquerque, NM, 87131); Black, W. C. *Fed Proc* 38(3, part 2): 1353; 1979. (no refs)

- 79-1743 Radiation Exposures of Hanford Workers: A Critique of the Mancuso, Stewart and Kneale Report.** (Eng) Anderson, T. W. (Dept. Preventive Medicine and Biostatistics, Faculty Medicine, Univ. Toronto, Ontario, Canada). *Health Phys* 35(6): 743-750; 1978.

A published analysis of Hanford (Washington) nuclear plant mortality data based mainly on a case/control comparison of mean cumulative radiation records in cancer vs noncancer deaths of Hanford employees is critically reviewed. The analysis indicated the occurrence of approx 25 radiation-induced cancers, mainly cancers of the reticuloendothelial system (RES), especially myeloid leukemia and myeloma. A second analysis, based on a proportionate mortality comparison of the Hanford deaths with general US mortality patterns, appeared to confirm this conclusion. This second analysis, however, was not carried out using age-adjusted mortality rates. In addition, both the corrected and uncorrected figures contradicted the main analysis, indicating an apparent deficit in deaths from leukemia (the cancer most likely to be increased by exposure to external ionizing radiation) as well as from total RES cancers. The main analysis was based on mean cumulative exposures that were distorted by a few abnormally high figures, leading to implausible estimates of excess deaths. The two methods, however, were consistent in indicating some excess deaths from myeloma, cancer of the pancreas, and possibly cancer of the lung, in addition to the deficit in leukemia deaths. Previous experience with ionizing radiation has not shown it to be particularly liable to induce myeloma or pancreatic cancer. An investigation of the work histories of these cases might yield some insight into another

occupational or non-occupational cause of these two diseases. (6 refs)

- 79-1744 Impact of Long-Term Filter Cigarette Usage on Lung and Larynx Cancer Risk: A Case-Control Study.** (Eng) Wynder, E. L. (Div. Epidemiology, Naylor Dana Inst. Disease Prevention, American Health Foundation, 320 E. 43d St., New York, NY, 10017); Stellman, S. D. *J Natl Cancer Inst* 62(3): 471-477; 1979.

A case-control study was conducted among 1,034 white male and female hospital patients in six US cities with histologically proved lung cancer (Kreyberg type 1, squamous and rat cell types; 684 patients) or larynx cancer (350 patients). After adjustment for duration of smoking habit, inhalation, and butt length, relative risks of developing lung or larynx cancer were consistently lower among long-term smokers of filter cigarettes than among smokers of nonfilter cigarettes, irrespective of quantity smoked. Relative risks in all groups declined with increased years of smoking cessation. The observed risk reduction among current smokers of filter cigarettes was consistent with that expected, considering that these persons had smoked the older high-tar nonfilter cigarettes for a large proportion of their lives. (35 refs)

- 79-1745 Bronchial Cancer in Hong Kong 1976-1977.** (Eng) Chan, W. C. (Dept. Pathology, Univ. Hong Kong, Queen Mary Hosp., Hong Kong); Colbourne, M. J.; Fung, S. C.; Ho, H. C. *Br J Cancer* 39(2): 182-192; 1979.

The relationship between smoking and bronchial cancer among the Chinese in Hong Kong was studied between 1976 and 1977 with the use of 208 men and 189 women with cancer and 204 male and 189 female controls. Among the cancer patients, 20% fewer men and 30% fewer women were nonsmokers and 24% more men and 20% more women were heavy or very heavy smokers compared with controls. Among the men there was no indication that type of cancer was related to the amount smoked, whereas among women there was an increased relative risk for squamous and small cell anaplastic carcinomas associated with heavy or very heavy smoking. Adenocarcinomas and large cell anaplastic carcinomas occurred more often in men <50 yr old than among older men. The occurrence of bronchial cancer among nonsmoking women (nearly half of the female patient population) could not be attributed to lying about smoking habits, misdiagnosis, age, occupation, education, marital status, age at first marriage, number of children, place of origin, place of residence, or passive exposure to tobacco smoke. More female cancer patients used kerosene or gas for cooking than did controls, but 15 nonsmoking cancer patients did not cook at all. The cause of cancer in the nonsmoking women remains unknown. (15 refs)

- 79-1746 Pleural Plaques in a Health Survey Material: Frequency, Development and Exposure to Asbestos.** (Eng) Hillerdal, G. (Dept. Lung Medicine, Univ. Hosp., S-750 14 Uppsala, Sweden). *Scand J Respir Dis* 59(5): 257-263; 1978.

Mass x-ray screening of residents in Uppsala County (population 230,000), was undertaken in order to detect individuals with hyaline pleural plaques (PP). A total of 508 cases, 492 of whom were men, were found during 1970-1976. Of the 369 men in whom a history was taken, 79.4% had been exposed to asbestos (most via occupation) and 78.9% were smokers or had smoked at the time of asbestos exposure. The mean latency time from first exposure to asbestos and first x-ray evidence of PP was 32.7 yr in the 217 men for whom these data were available. PP were found almost exclusively in men over 40, with the highest frequency occurring in men in the age group 60-64 yr. Bronchial carcinoma developed in 3/492 men after the diagnosis of PP had been made. All three were heavy smokers. Pulmonary fibrosis occurred in 19 men. A history was obtained in 15/16 women, and in 8/15 there were strong reasons to suspect that the PP originated from asbestos. (21 refs)

- 79-1747 Primary Lung Cancer. A Retrospective Study.** (Nor) Rostad, H. (Kirurgisk avdeling A, Rikshospitalet, Norway); Vale, J. R. *Tidsskr Nor Laegeforen* 98(33): 1670-1673; 1978.

A series of 1,053 lung cancer patients (895 men and 158 women) treated over a 10-yr period was studied retrospectively. The incidence was highest in the age bracket 50-70 yr for both men and women. Smoking habits were not established for 29% of the women and 19% of the men. Among the remainder, 33% of the women and 76% of the men were smokers. Squamous epithelial carcinoma was diagnosed in 238 cases, undifferentiated carcinoma in 77, small cell anaplastic carcinoma in 56, adenocarcinoma in 133, carcinoid tumors in 21, and other tumors in 19; 509 cases were not classified histologically. (14 refs)

- 79-1748 The Significance of Cancerogeneous Noxes in the Formation of Pulmonary Hamartochondromas as Compared to Carcinomas and Sarcomas of the Lung.** (Ger) Gebauer, C. (Bezirkskrankenhaus für Lungenkrankheiten Zschadras, Altmarkt 14, DDR-801 Dresden, E. Germany). *Arch Geschwulstforsch* 4(48): 761-769; 1978.

The roles of carcinogens and other factors in the development of pulmonary cancer were studied in 104 cases of pulmonary hamartochondromas occurring in 1961, and in 41 cases of primary pulmonary sarcoma occurring between 1957 and 1974. All cases were seen at a single clinic in Zschadras, East Germany. Of the patients with pulmonary carcinoma, 90.6% were men, and 89.7% smoked cigarettes (76.5% were heavy smokers). Of the patients with hamartochondromas, 80% were men, and 91.4% were cigarette smokers (68.8% heavy

EPIDEMIOLOGY AND BIOMETRY

smokers). Only 48.8% of the patients with pulmonary sarcoma were men, and 70% were smokers (21.4% heavy smokers). Coexistent chronic bronchitis occurred in 58.3% of patients with pulmonary carcinoma, in 45.2% of patients with hamartochondroma, and in 24% and 13.2% of patients with pulmonary adenocarcinoma and sarcoma, respectively. The percentage of men with hamartochondromas who were exposed to radiation was higher than that of men with carcinoma (33.7% vs 13%). (38 refs)

79-1749 Lung Cancer Mortality and Hydrogen Sulfide Sources in Southeastern Coastal States (Meeting Abstract). (Eng) Hitchcock, D. R. (Hitchcock Association, Farmington, CT, 06032). *Fed Proc* 38(3, part 2): 1270; 1979. (no refs)

79-1750 Opium and Oesophageal Cancer in Iran (Letter to Editor). (Eng) Hewer, T. F. (Vine House, Henbury, Bristol, England). *Lancet* 1(8106): 45; 1979.

A previous suggestion that the presence of mutagenic substances in sukhteh (prepared from scrapings of tar from opium pipes) might be a cause of esophageal cancer among Iranians who chew it is defended. The criticism was based on the belief that <5% of the cancer patients used opium. In contrast, it appears that >60% of these patients actually use the narcotic. (no refs)

79-1751 Are Patients Who Are Less Susceptible to Impairment of Pulmonary Function by Smoking More Predisposed to Development of Gastric Cancer? (Meeting Abstract). (Eng) Luk, G. D. (Dept. Medicine and Epidemiology, Johns Hopkins Univ. Sch. Medicine and Hygiene, Baltimore, MD); Meyer, M. B. *Clin Res* 26(4): 613A; 1978. (no refs)

79-1752 Correlation Between Nutrition and Mortality due to Some Chronic Degenerative Diseases. (Ger) Ulbricht, G. (Zentralinstitut für Ernährung, Akademie der Wissenschaften der DDR, Arthur-Scheunert-Allee 114/116, DDR-1505 Potsdam-Rehbrücke, E. Germany); Haenel, H.; Oehmsch, W.; Erhardt, V. *Z Gesamte Hyg* 24(12): 929-934; 1978.

Correlations between the crude standardized mortality rates for 12 diseases and nutrition were analyzed for 18 industrialized countries. Negative correlations were found between gastric cancer and the consumption of animal protein, fat, fatty acids, cholesterol, and milk. Positive correlations were found between gastric cancer and the consumption of cereal products and complex carbohydrates. The correlations were weak in the age bracket 15-35 yr, becoming more significant in middle age, and disappearing after 75 yr in both men and women. The correlations were always weaker for women than for men. Negative correlations were found between in-

testinal cancer mortality and the consumption of vegetable protein, complex carbohydrates, and cereal products. Positive correlations were seen between intestinal cancer mortality and the consumption of fat, cholesterol, sugar, meat, eggs and beer. The sex differences were negligible. Correlations were seen only in the age group >35 yr in men and >45 yr in women, and they intensified with advancing age. (8 refs)

79-1753 Gastric Carcinoma in the Dutch Province of Zeeland: An Epidemiological Study. (Dut) Bijlsma, F. (Pathologisch-Anatomisch Laboratorium, Streeklaboratorium Zeeland, Middelburg, Netherlands); Planteydt, H. T. *Ned Tijdschr Geneesk* 122(51): 2013-2020; 1978.

The incidence of gastric cancer in the Dutch province of Zeeland was studied epidemiologically using data on 392 patients recorded during 1961-1970 in a central registry in Middelburg. Striking local differences were observed, and these differences were even more apparent when mortality data for this period were compared with those for the previous years. Data on patient age, sex, and histological type of tumor did not diverge greatly from the parameters for the disease in general. (10 refs)

79-1754 Pancreas Cancer. I. Duct Adenocarcinoma. A Clinical-Pathologic Study of 380 Patients. (Eng) Cubilla, A. (No affiliation given.); Fitzgerald, P. J. *Pathol Annu* 13(1): 241-289; 1978.

A detailed clinical-pathologic study of 380 patients with duct cell adenocarcinoma, the most common type of pancreas cancer, is reported. The peak number of patients were in their 70's for both sexes, with a male/female ratio of 1:5. White patients predominated (92%), and the most prevalent religion was Jewish (42%). Sixty-eight percent of the men and 25% of the women were smokers and 24% of the men and 4% of the women were alcoholics. Of the 14 men who were simultaneously heavy smokers and excessive drinkers, three had a second primary tumor and two of these were alcohol-tobacco-associated cancers. Diabetes occurred in 119 patients and thromboembolic disease in 55. In 31% of the patients, there was a history of cancer in the immediate family. About two-thirds of the patients presented with jaundice and elevated liver enzymes. In 80% of patients, the cancer was localized to one site: head of the pancreas, 61%; body, 13%; and tail, 5%. Staging of 333 patients indicated that 14% were stage I, 21% were stage II, and 65% were stage III cases. All pancreas cancers tended toward regional intraabdominal spread when seen clinically or at exploratory operation. At autopsy metastases to the liver and lymph nodes were seen in 70%-80% of patients. Clinical presentation as metastasis in peripheral lymph nodes, skin, or bones from an inapparent primary was seen in 13% of the patients. Tumor size and stage were closely correlated in many cancers. The overall mean survival period was 4 mo, irrespective of treatment. (115 refs)

- 79-1755** Carcinoma of the Colon and Rectum in North-East Scotland. (Eng) Kyle, J. (Woodend General Hosp., Aberdeen, Scotland); Petrie, M. X. *J R Coll Surg Edinb* 24(1): 22-27; 1979.

A recent analysis revealed that Scotland, particularly the northeast region, has the highest death rate in the world for colon carcinoma and that it ranks sixth for rectal carcinoma. To obtain a true picture of these diseases in a relatively closed community, every patient with carcinoma of the colon or rectum admitted to Aberdeen hospitals during 1975 was interviewed. Only patients permanently residing in Aberdeen or in three adjacent counties were included in the series. During 1975, 202 new cases of colorectal carcinoma were diagnosed, an incidence of 51.8/100,000. There were 100 men and 102 women. None of the patients were < 30 yr old; 87 were aged 50-69, 93 were aged 70-89. The chances of a man > 50 yr old developing a tumor were much greater in all sites except the transverse colon. The concept that carcinoma of the right colon is commoner in women needs to be revised. Even younger men were more likely than women to have rectal carcinoma. The risk increased steadily at all sites with age. Only 13 patients gave a definite history of large bowel carcinoma in a first-degree relative. For men, the incidence (per 100,000) was 110.9 in the city and 93.4 in rural areas; these values women for were 96.0 and 80.2, respectively. Thus, risk of large bowel cancer was greater in city dwellers in Northeast Scotland than among rural dwellers. The latter may consume larger quantities of vegetables such as cabbage and turnips, which may speed up intestinal transit time. The benzpyrene hydroxylase in these vegetables may break down some potential carcinogens in the gut. It was hard to determine the complete occupational history of many of the men. Most of the women were housewives. Great difficulty was also experienced in recording dietary habits. (14 refs)

- 79-1756** Epidemiological Report on Rectal Cancer. (Ger) Magyar, K. (Abteilung Gesundheits- und Sozialwesen, Rat der Stadt Halle, DDR-409 Halle-Neustadt, E. Germany); Heindorf, J.; Berger, H. J. *Z Gesamte Hyg* 24(12): 944-946; 1978.

Epidemiological data on the occurrence of rectal cancer in the Halle region of East Germany during 1953-1962 are presented. The incidence, per 100,000 inhabitants, was 13.7 in 1953, and 14.7 in 1956 and 1962. Rectal cancer accounted for 4.5% of all tumors in 1953 and for 4.4% in 1962. A total of 428 cases were diagnosed: 208 in men and 220 in women. The incidence was highest in the age bracket 60-80 yr in both sexes. (11 refs)

- 79-1757** Assuring the Quality of Questionnaire Data in Epidemiologic Research. (Eng) Gordis, L. (Dept. Epidemiology, Johns Hopkins Sch. Hygiene and Public Health, 615 N. Wolfe St., Baltimore, MD, 21205). *Am J Epidemiol* 109(1): 21-24; 1979.

The quality of questionnaire or interview data in epidemiologic research is a matter of concern. Problems in eliciting valid histories are further compounded by (1) the variability in the interview or questionnaire instruments used in different studies and (2) the impossibility of assessing the comparability of these studies because of the lack of sufficient information on these instruments in published papers. Steps to improve the quality of the data are listed. (2 refs)

- 79-1758** Epidemiologic Data for Environmental Determination of Urinary System Tumours and Nephropathy in an Endemic Region. (Eng) Chernozemsky, I. N. (Inst. Oncology, Medical Acad., Sofia 1156, Bulgaria); Petkova-Bocharova, T.; Stoyanov, I. S.; Nikolov, I. G. *Arch Geschwulstforsch* 48(8): 756-760; 1978.

The familial pattern and time clustering of patients with urinary system tumors (UST; 138 patients), endemic neuropathy (EN; 714), and UST + EN (55) diagnosed in nine hyperendemic villages in the Vratza district of Bulgaria during 1965-1976 were examined. There were 144 spouses among these patients, and nearly 50% of them came from nonendemic families or villages. Among the 907 cases, 471 were blood relatives; 799 familial relationships were encountered, because some people had more than one relative: 165 persons were parents and children, 254 siblings, 215 second-degree relatives, and 165 third-degree relatives. In 21% of the 91 parent-child pairs the offsprings were diagnosed before the parent, and in 14% they were diagnosed in the same year. Among the 166 pairs of siblings, 19% were diagnosed in the same year and in 33% the younger was diagnosed first. These data indicate that the relatives under study did not reveal any familial pattern specific for an inheritance of the diseases. Their pattern followed, rather, the size of the population at greater risk; ie, persons 40-60 yr old, particularly women, indicating a decisive role for environment in the etiology of both diseases. This hypothesis is supported by data showing a closer proximity in time of onset than in age of onset of the diseases among first-degree relatives. (22 refs)

- 79-1759** Liver Oncogenesis and Steroids. (Eng) Christopherson, W. M. (Dept. Pathology, Health Sciences Center, Univ. Louisville, Sch. Medicine, Louisville, KY); Mays, E. T.; Barrows, G. H. *In: Prog Clin Cancer* 7: 153-163; 1978.

One hundred and forty-eight cases of liver tumors, most of which were associated with oral contraceptives, were reviewed with regard to relationship to steroids and type of steroid, patient age, signs and symptoms, tumor classification, gross and histopathologic findings, treatment, pathogenesis, and risk factors. Most tumors were benign, but 19 were hepatomas. The biological potential of benign liver tumors is briefly discussed. (38 refs)

- 79-1760** Hepatocellular Carcinoma, Hepatitis B and Measles (Letter to Editor). (Eng) Ree, G. H.

(Hosp. Tropical Diseases, London, England). *Br J Cancer* 39(2): 205-206; 1979.

Sixteen Africans with hepatitis B surface antigen (HBsAg)-associated primary hepatocellular carcinoma (PHC) were studied to determine whether they had measles antibody levels greater than those of normal controls and, thus, whether these levels could be used as a possible marker of previous chronic liver disease in the genesis of PHC. Four patients had no serological evidence of past measles, and measles antibody levels in the HBsAg-positive patients were no higher than those in 16 normal, HBsAg-negative controls. (7 refs)

79-1761 Hepatitis B Virus Infection in Southern African Blacks with Hepatocellular Cancer. (Eng) Kew, M. C. (Dept. Medicine, Univ. Witwatersrand Medical Sch., Hospital Hill, Johannesburg 2001, S. Africa); Desmyter, J.; Bradburne, A. F.; Macnab, G. M. *J Natl Cancer Inst* 62(3): 517-520; 1979.

Sera from 289 southern African blacks with histologically proved hepatocellular carcinoma (HCC) were tested for hepatitis B surface antigen (HBsAg) and its specific antibody, anti-HBs, in order to determine whether there is an association between hepatitis B virus (HBV) infection and HCC in these people. HBsAg was present in the sera of 61.6% of the patients compared with only 11.3% of age-matched, sex-matched, and ethnically matched controls ($2 < 0.001$). Anti-HBs was found in 17% of the patients and 41.7% of the controls ($p < 0.001$). In 74 patients studied in more detail, antibody against hepatitis B core antigen (anti-HBc) was detected in 89%, almost always in high or moderately high titer. Anti-HBc was found in 37.5% of the controls. Active HBV infection, as indicated by positive tests for HBsAg or anti-HBc, was present in 91% of the patients compared with 39.4% of the controls ($p < 0.001$). Hepatitis B envelope (e) antigen was detected in 2.3% and its specific antibody in 20.5% of the patients. The corresponding figures in the controls were 0% and 55%. HBs antigenemia was more common in younger patients with HCC. No relationship was demonstrated between α -fetoprotein and HBs antigenemia. HBV infection was equally common in patients with and without cirrhosis in the nontumorous liver. (36 refs)

79-1762 Age of Parents of Children with Nephroblastoma (Letter to Editor). (Fre) Spira, A. (IN-SERM, 16 bis, av. P.-Vaillant-Couturier, 94800 Villejuif, France); Lemerle, J.; Lazar, P. *Rev Epidemiol Sante Publique* 26(4): 361-362; 1978.

A statistical study of the age of mothers and fathers at the time of birth of children who later developed a nephroblastoma revealed no relationship. The study involved 209 children with nephroblastoma hospitalized during 1960-1970. (3 refs)

79-1763 Changing Patterns in Age Distribution of Renal Carcinoma Patients. (Eng) Noronha, R. F. (Dept. Urology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX); Johnson, D. E.; Guinee, V. F.; Borlase, B. C. *Urology* 13(1): 12-13; 1979.

The age distribution of renal carcinoma patients admitted to a Houston, Texas, hospital between 1957 and 1976 was reviewed. Of the 890 patients included in the study, 79.6% were aged 40-69 yr. There was a significantly increased representation of patients aged 40-69 yr in each 5-yr period within the 20-yr study period; there was no relative increase in the proportion of patients aged 50-59 yr or 60-69 yr. The proportion of patients aged 40-49 yr increased steadily from 1957 to 1971, but began to decrease from 1972 to 1976. (6 refs)

79-1764 Effect of Age on Incidence of Breast Cancer in Females. (Eng) Moolgavkar, S. H. (Fox Chase Cancer Center, 7701 Burholme Ave., Philadelphia, PA, 19111); Stevens, R. G.; Lee, J. A. *J Natl Cancer Inst* 62(3): 493-501; 1979.

Incidence and mortality data on breast cancer (BC) in women from various Western and Japanese populations were compared. Incidence data were examined for Connecticut (1935-1972), Denmark (1943-1967), Iceland (1911-1969), and Osaka (1963-1975). Mortality data were examined for the US white female population (1931-1970), England and Wales (1911-1970), Canada (1931-1970), and Japan (1947-1975). Six models were tested against the data: the first was a simple generation-effects model, and each subsequent model introduced a specific type of interaction between the age and cohort effects. After adjustment for birth cohort and year of event (incidence or mortality), the age curves from all the Western populations were similar in shape. The age curve for the Osaka incidence was similar in shape to the Western incidence curves. The Osaka curve continued to increase after menopause (MP); the post-MP decrease in rates in individual cross sections was the result of a strong cohort effect. Cohort influences are most prominent in a population in which BC incidence is changing from a low-risk profile to a high-risk profile. In a population already at high risk, secular trends in BC incidence are caused by more subtle interactions of age and cohort. The pre-MP mortality curve for Japan was similar in shape to the Western curves; however, the post-MP Japanese mortality curve had a smaller slope at each point. (50 refs)

79-1765 Epidemiology of Breast Carcinoma: Age, Menstrual Status, and Exogenous Hormone Usage in Patients with Lobular Carcinoma In Situ. (Eng) Rosen, P. P. (Dept. Pathology, Memorial Hosp., 1275 York Ave., New York, NY, 10021); Senie, R. T.; Farr, G. H.; Schottenfeld, D.; Ashikari, R. *Surgery* 85(2): 219-224; 1979.

The relationship of age, menstrual status, and exogenous hor-

mone usage to lobular carcinoma in situ (LCIS) was studied in 59 women with LCIS and 190 controls with ductal carcinoma. Thirty-nine patients had LCIS only; the other 20 had another form of carcinoma in the ipsilateral or contralateral breast in addition to LCIS. Of the 39 patients who had LCIS only, 22 were premenopausal (pre-MP), 8 were menopausal (MP), and 9 were postmenopausal (post-MP) at the time of diagnosis. Five pre-MP, three MP, and two post-MP women reported hormone usage. Of the seven patients with LCIS plus infiltrating lobular carcinoma, one was pre-MP, one was MP, and five were post-MP; three of the post-MP patients reported hormone usage. Of the 13 patients with LCIS and ductal carcinoma, 5 were pre-MP, 2 were MP, and 6 were post-MP; none reported having used hormones. Five of the 15 controls with intraductal carcinoma were pre-MP, 4 were MP, and 6 were post-MP; 6 had used hormones. Of the 175 controls with infiltrating ductal carcinoma, 35 were pre-MP, 32 were MP, and 108 were post-MP; 61 had used hormones. The data suggest that LCIS is an estrogen-dependent lesion at its inception, but all lesions may not be equally dependent on estrogens at all stages. (23 refs)

- 79-1766 Cancer in Married Couples.** (Eng) Payan, H. M. (Dept. Pathology, Bell Memorial Hosp., Ishpeming, MI, 49849). *South Med J* 72(1): 17-19; 1979.

A review of 2,512 cancer admissions in a small community hospital during a 10-yr period revealed 19 married couples with cancer. Two couples had the same type of cancer originating from the same organ (carcinoma of the breast and transitional cell carcinoma of the bladder), and 10 couples had tumors of the same histopathologic type. In 15/19 cases the cancer developed first in the wife, although the wives were younger. All 19 couples had lived together for an av of 37 yr before the first cancer was discovered. The findings underscore the importance of environment in cancer etiology. (20 refs)

- 79-1767 Pituitary Adenoma and Oral Contraceptives: A Case-Control Study.** (Eng) Coulam, C. B. (Dept. Obstetrics and Gynecology, W-10, Mayo Clinic, 200 First St., S.W., Rochester, MN, 55901); Annegers, J. F.; Aboud, C. F.; Laws, E. R.; Kurland, L. T. *Fertil Steril* 31(1): 25-28; 1979.

A case-control study was made of nine female residents of Olmsted County, Minnesota, with pituitary adenoma diagnosed between 1971 and 1977. The study was made to determine whether the use of oral contraceptives or some other etiologic factor is associated with the increasing incidence of this tumor in Olmsted County women of childbearing age. There were four controls for each patient. In this limited series, the use of oral contraceptives did not appear to be associated with the development of pituitary adenoma. Nulligravidity and nulliparity were more prevalent among the tumor patients than among the controls; smoking prior to diagnosis was reported by 5/9 patients and 16/36 controls. Other

risk factors were uncommon in both groups. Unless other etiologic agents can be identified, it appears that the increasing incidence of pituitary adenoma is due to advances in diagnostic and surgical technology rather than to a specific etiologic factor. (12 refs)

- 79-1768 The True Cancer Risk of Estrogens.** (Eng) Martin, P. L. (Dept. Obstetrics and Gynecology, Univ. California at San Diego Sch. Medicine, San Diego, CA). *Cancer Cytol* 18(2): 19-23; 1978.

The mortality experience of 159 uterine cancer patients seen in a private practice over a 30-yr period was investigated retrospectively to determine the true cancer risk of estrogen therapy. Outcome was established for 144 patients, and survival for 5 yr was considered a cure. Diagnosis was established primarily by endometrial biopsy or by dilation and curettage. Of 110 patients on long-term estrogen use before diagnosis (EU), only 1 died of recurrent cancer in <5 yr. Of 47 patients with no history of estrogen use (NEU), 7 died of recurrent disease. (Two patients whose past estrogen use could not be determined were dropped from the study.) In EU patients, diagnosis was made at an earlier stage of disease (64.2% diagnosed in situ vs 47.8% of the NEU group), and they were more likely to have a well-differentiated tumor grade than NEU patients (60% EU were Grade I vs 40% NEU). The EU patients were required to see their physicians at fairly regular intervals to obtain estrogen prescription refills and they generally reported abnormal bleeding more promptly. In the one EU patient who died, there was a change from a noninvasive well-differentiated cellular pattern found at hysterectomy to an undifferentiated pattern found at recurrence. This study indicates that estrogens, when needed, can be prescribed and monitored with reasonable safety. (6 refs)

- 79-1769 Replacement Estrogens and Endometrial Cancer.** (Eng) Jick, H. (Boston Collaborative Drug Surveillance Program, 400 Totten Pond Rd., Waltham, MA, 02154); Watkins, R. N.; Hunter, J. R.; Dinan, B. J.; Madsen, S.; Rothman, K. J.; Walker, A. M. *N Engl J Med* 300(5): 218-222; 1979.

The relationship between endometrial cancer and replacement estrogen use was investigated in a comprehensive health-care organization. Between July, 1975 and July, 1977, there was a sharp decrease in the incidence of endometrial cancer that paralleled a substantial reduction in prescriptions for replacement estrogens. Incidence rates were estimated for estrogen users and nonusers among women 50 to 64 yr old with intact uteri; current long-term users had an annual risk for endometrial cancer of 1%-3%, whereas nonusers had a risk less than one-tenth as great. These incidence rates remained fairly constant over time among users and nonusers; the drop in overall incidence soon after estrogen use declined, suggests that the increased risk associated with estrogens falls quickly after discontinuation. The reduction in incidence of

endometrial cancer in this group practice was part of a general decline in the United States after 1975. (15 refs)

- 79-1770 Carcinoma of the Prostate--An Epidemiological Report.** (Ger) Magyar, K. (Abteilung Gesundheits- und Sozialwesen, Rat der Stadt Halle, DDR-409 Halle-Neustadt, E. Germany); Heindorf, J.; Richter, C. *Z Gesamte Hyg* 24(12): 946-948; 1978.

Three hundred and twenty-four new cases of prostate carcinoma were diagnosed in the Halle area of East Germany during 1963-1972. The morbidity was 9.33/100,000 in 1963, 15.72/100,000 in 1971, and 15.55/100,000 in 1972, indicative of an increasing trend. Prostate carcinoma accounted for 2.65% of all tumors in 1963 and for 3.46% in 1972. Most patients were in the age bracket 60-80 yr at the time of diagnosis. (13 refs)

- 79-1771 Health Effects of Energy-generating Sources (2 Letters to Editor).** (Eng) Schaefer, W. W. (Sheboygan Orthopaedic Associates, SC, Sheboygan, WI); Jones, R. J. *JAMA* 241(7): 693-695; 1979.

A report by the American Medical Association Council on Scientific Affairs in which the health effects of various energy-generating sources on employees of industry and on the general public were evaluated is criticized on several counts. The study made comparisons between the most hazardous use of coal and the most favorable use of nuclear fission. Only three sources of basic statistics were used, and all three originated from the nuclear and electrical utility industry. There were no statistics on the possibility of a nuclear power plant accident with a large release of radioactivity. A rebuttal by a member of the council follows. (5 refs)

- 79-1772 Neonatal B.C.G. Vaccination and Childhood Cancer (Letter to Editor).** (Eng) Nilsson, B. S. (Dept. Thoracic Medicine, Karolinska Hosp., S-104 01 Stockholm 60, Sweden); Widstrom, O. *Lancet* 1(8109): 222; 1979.

To determine the possible effect of BCG vaccination on tumor incidence, the number of malignancies occurring in Swedish children born during 1976-1977, the year following the discontinuation of general BCG vaccination in neonates, was compared with that in children born during 1971-1972 and 1973-1974. Tumor rates for children born during 1971-1972, 1973-1974, and 1976-1977 were 17.6, 27.3, and 19.0/100,000 births, respectively, a finding that does not support the notion that BCG vaccination influences tumor incidence. (8 refs)

- 79-1773 Schizophrenia and Malignant Neoplasms in a North Swedish Population (Letter to Editor).** (Eng) Modrzewska, K. (Inst. Medical Genetics, S-752 20

Uppsala, Sweden); Book, J. A. *Lancet* 1(8110): 275-276; 1979.

Deaths due to malignant neoplasms in a North Swedish population characterized by a high degree of inbreeding and a high incidence of schizophrenia were examined. Between 1950 and 1970, 166/1,359 deaths were caused by malignancies; this ratio of 122/1,000 was significantly lower than that in the general Swedish population (163/1,000, $p < 0.003$). A biochemical and genetic link (involving perhaps catecholamine or methionine metabolism) between schizophrenia and reduced cancer risk is hypothesized. (7 refs)

- 79-1774 Morbidity Experience of Air Traffic Control Personnel--1967-1977.** (Eng) Booze, C. F. (Civil Aeromedical Inst., FAA Aeronautical Center, Oklahoma City, OK, 73125). *Avia Space Environ Med* 50(1): 1-8; 1979.

Examination of the 1967-1977 morbidity experience of 28,086 air traffic controllers (ATC) revealed that hypertension and psychoneurotic disorders were the most frequently occurring new diseases among these personnel. There was a lack of association between disease occurrence and occupation in data correlating disease occurrence with length of service and age. Among 1,759 medical disqualifications among ATC personnel during 1972-1977, malignancy ranked 9 out of 10, with a frequency of 17. (9 refs)

- 79-1775 Malignancies in Primary Immunodeficiency (ID) Diseases, with Special Emphasis on Lymphoreticular Neoplasia (Meeting Abstract).** (Eng) Frizzera, G. (Dept. Lab. Medicine and Pathology, Univ. Minnesota Medical Sch., Minneapolis, MN, 55455); Rosai, J.; Dehner, L. P.; Spector, B. D.; Kersey, J. H. *Fed Proc* 38(3, part 2): 1273; 1979. (no refs)

- 79-1776 Malignant Lymphoma of Histiocytic Type and Exposure to Phenoxyacetic Acids or Chlorophenols (Letter to Editor).** (Eng) Hardell, L. (Dept. Oncology, Univ. Hosp., S-901 85 Umea, Sweden). *Lancet* 1(8106): 55-56; 1979.

Fourteen of 17 patients with histiocytic-type malignant lymphoma admitted to the oncology department of one hospital during a 3-mo period reported current or prior employment at a job in which exposure to phenoxyacetic acids or chlorophenols may have taken place. Eleven patients reported definite exposure to the chemicals. All but 1/11 patients were exposed to chemicals containing dibenzodioxin or dibenzofuran contaminants. (4 refs)

- 79-1777 The Incidence of Head Trauma and Subsequent Risk of Seizures and Brain Tumors**

(Meeting Abstract). (Eng) Annegers, J. F. (Rochester, MN); Kurland, L. T.; Grabow, J. D.; Groover, R. V.; Laws, E. R. *Neurology (Minneapolis)* 29(4): 578; 1979. (no refs)

79-1778 Thymectomy and Cancer: A Further Report.

(Eng) Vessey, M. P. (Dept. Social and Community Medicine, Oxford Univ., Oxford, England); Doll, R.; Norman-Smith, B.; Hill, I. D. *Br J Cancer* 39(2): 193-195; 1979.

Of 419 patients who had undergone thymectomy from myasthenia gravis (MG) in selected London hospitals between 1942 and 1964, 381 were followed up through 1972. Compared with the expected value (29.8), there was a small but significant increase in the number of deaths due to all causes other than MG and thymoma (42) among these patients. Deaths due to extrathymic tumors alone were nonsignificantly increased (11 vs 8.8 expected). The most notable feature was the occurrence of seven of these deaths 10-14 yr after thymectomy, compared with only 1.9 expected. No particular type of tumor tended to develop after thymectomy, and there was no evidence that adult thymectomy was followed by an increased risk of neoplastic disease. A previous study of 2,000 patients with MC indicated that this disease itself is associated with an increased cancer risk that is reduced by thymectomy. The present study tends to negate the concept of immunologic surveillance against neoplasia. (3 refs)

79-1779 Growth Kinetics and Collagen Synthesis of Normal Skin, Normal Scar and Keloid Fibroblasts In Vitro. (Eng) Diegelmann, R. F. (Div. Plastic Surgery, Dept. Surgery, Virginia Commonwealth Univ., Medical Coll. Virginia, Richmond, VA, 23298); Cohen, I. K.; McCoy, B. J. *J Cell Physiol* 98(2): 341-346; 1979.

The growth kinetics and collagen synthesis of normal skin, normal scar, and keloid fibroblasts (FB) were studied in vitro. The mean age of the 18 keloid subjects (16 women, 4 men) was 24 yr, and all were black. Most of the keloids were from the ear lobes and the upper thorax or face. The normal skin and normal scars were from 20 subjects (11 women, 9 men) with a mean age of 35 yr; 8 were black. All normal skin and normal scars were from the facial and abdominal regions following scar revision or aesthetic surgery. The growth kinetics were the same for all groups on days 2-12. However, the keloid FB consistently synthesized two to three times more collagen per cell than either normal skin or normal scar FB

during all growth phases. There was no significant difference in absolute or relative collagen synthesis when normal skin FB from black subjects were compared with those of white subjects. However, FB derived from normal-appearing skin adjacent to keloids in two subjects had a lower level of collagen synthesis per FB than the keloid-derived FB. It is possible that: (1) keloid FB are derived from one mutant cell (monoclonal) in response to injury; (2) keloid FB have an increased differentiated capacity to synthesize collagen in response to injury secondary to mechanical or hormonal influences; or (3) keloid FB have lost the capacity to respond to a feedback signal that controls collagen synthesis during normal wound healing. - 79-1782 The Effects of Neonatal Tactile Stimulation on the Adult Response to Ehrlich Carcinoma in Mice.** (Eng) Dechambre, R. P. (Service d'Experimentation Animale, Institut Gustave-Roussy, 94800 Villejuif, France); LaBarba R. C. *IRCS Med Sci (Cancer)* 6(11): 472; 1978.

The effect of neonatal tactile stimulation (brushing with a sable hair brush) on the survival of C57Bl/6 mice injected with Ehrlich ascites tumor cells (5×10^6 cells) was studied. Each experimental animal was brushed daily for 10 days beginning the day after birth; controls were not brushed. Tumor cell inoculation was performed on day 48 ± 3 . The mean survival time was 24.00 days in the control group and 26.55 days in the stimulated group; the difference was significant. By 24 days after tumor inoculation, 60% of the controls and 30% of the stimulated animals had died. Thus, neonatal tactile stimulation resulted in a longer survival time after tumor graft in the adult. The data support the concept that early experience influences receptivity to transplanted tumors. (6 refs)

- 79-1783 Heterotransplantation of Human Stomach Carcinoma in Nude Mice.** (Eng) Suzuki, K. (Lab. Experimental Animals, Inst. Medical Science, Univ. Tokyo, Shiroganedai 4-6-1, Minato-ku, Tokyo 108, Japan); Sudo, K. *Gann* 70(1): 109-114; 1979.

The growth patterns of 35 primary human stomach tumors and 14 metastatic lymph nodes in nude mice were studied following sc or im transplantation. Sixteen of the primary tumors and five of the metastatic lymph nodes grew in the nude mice. Tumor takes were observed with papillary adenocarcinomas, well- and moderately well-differentiated tubular adenocarcinomas, and poorly differentiated adenocarcinomas; transplantations of mucinous adenocarcinomas, signet-ring cell carcinomas, and one adenosquamous carcinoma were unsuccessful. The histologic appearances of almost all tumors growing in the nude mice resembled those of the primary tumors. The transplants showed well-circumscribed growth patterns without aggressive invasion, especially after im transplantation. Eight tumors were maintained in serial passage for 20-39 transfers. Metastatic tumor growth in the distant lymph nodes was observed in one mouse with a primary tumor transplant and in two mice with metastatic node transplants. (7 refs)

- 79-1784 Bile Acids LVIII. Bile Acids and Colorectal Cancer.** (Eng) Davis, J. W. (Dept. Biochemistry, St. Louis Univ. Sch. Medicine, 1402 South Grand Boulevard, St. Louis, MO, 63104); Elliott, W. H. *Lipids* 13(12): 976-981; 1978.

The effects of altering the flow of bile into duodenum and of feeding diets with different lipid concentrations on the volume of bile secreted and on biliary bile acid concentrations were studied in female Sprague-Dawley rats. Two cannulas were implanted in each animal to form an externalized bile duct through which bile was drained from the common duct and returned to the duodenum. The daily mean volume of bile secreted and the daily concentrations of biliary bile acids were increased by 50% when the bile was reinfused into the rat rather than drained away. Bile drainage also reversed the diurnal fluctuation in bile acid concentration observed during bile return. The diurnal variations were markedly reduced when bile was infused into the duodenum at a uniform rate during each 24-hr period. The bile acid concentration increased as the dietary lipid concentration was increased and decreased when the dietary lipid content was reduced. (11 refs)

- 79-1788 Correlation in the Proportion of Oleic to Vaccenic Acid of Plasma Phospholipids with the Early Stages of Hepatoma 7288CTC Growth.** (Eng) Mapes, J. P. (Dept. Biochemistry and Biophysics, Texas Agricultural Experiment Station, Texas A&M Univ. System, College Station, TX, 77843); Wood, R. *Lipids* 14(1): 70-71; 1979.

The major octadecanoate isomers oleate ($\Delta 9$) and vaccenate ($\Delta 11$) were measured in the plasma phospholipids of male Buffalo rats bearing hepatoma 7288CTC at 3-day intervals following hepatoma implantation. The percentage of vaccenate decreased from 45% of the octadecanoate fraction at day 0 to 25% by day 15 and remained at this level for the rest

of the 30-day experimental period. A significant decrease (from 45% to 35%) had occurred by day 6, well before the tumor could be detected. Therefore, early phases of hepatoma growth can be correlated with the decrease in the percentage of vaccinate. This change might have potential diagnostic value, because it can be measured in a small blood sample and because it occurs very early in the growth of the hepatoma. (10 refs)

- 79-1790 Altered Nucleosome Spacing in Newly Replicated Chromatin from Friend Leukemia Cells.** (Eng) Murphy, R. F. (Div. Biology, California Inst. Technology, Pasadena, CA, 91125); Wallace, R. B.; Bonner, J. *Proc Natl Acad Sci USA* 75(12): 5903-5907; 1978.

Evidence of a difference in repeat length between newly replicated and total chromatin from Friend leukemia cells (clone FSD-3) is presented. Staphylococcal nuclease digestion of DNA in isolated nuclei from cells labeled for 24 hr with ¹⁴C-thymidine and then for 10 min with ³H-thymidine indicated that the newly replicated chromatin was converted into nucleosomes at less than half the rate total chromatin is converted. This difference in digestion rate was suggested to be due to a difference in the structure of newly replicated chromatin. Polyacrylamide gel electrophoresis of nucleosomal DNA from cells labeled with ¹⁴C-thymidine for 24 hr followed by ³H-thymidine or 10 min showed that the internucleosomal spacer of newly replicated chromatin is approx 20 base pairs shorter than that of total chromatin. This difference may have implications for models of chromatin replication and transcription. (30 refs)

- 79-1791 Gastrulation in the Mouse; Assessment of Cell Populations in the Epiblast of *tw18/tw18* Embryos.** (Eng) Snow, M. H. (MRC Mammalian Development Unit, Wolfson House, Univ. Coll. London, 4 Stephenson Way, London NW1 2HE, England); Bennett, D. *J Embryol Exp Morphol* 47: 39-52; 1978.

Cell populations and mitotic activity were analyzed in embryos from seven mouse litters resulting from the mating of heterozygous mice (+/*tw18*) and taken on gestation days 6.25-7. Growth rate was analyzed by determining cell number increase and by mapping mitotic activity and planes of cleavage. Mutant (*tw18/tw18*) and normal embryos could be distinguished by morphological criteria in litters ≥ 6.75 days old. The mutant embryos were smaller but showed a very high overall mitotic activity, approx double that of their normal littermates. The mutant embryos also had a marked disorientation of the cleavage planes in most of the epiblast. In

preprimitive streak embryos (6.25 days), before any gross abnormality was detectable, two types of embryo were seen. One was comprised of small embryos that also showed the mitotic disturbances seen in the later-stage mutants, and the other consisted of larger embryos that did not show mitotic abnormalities. This observation indicates that the *tw18* allele acts several hours before primitive streak formation. There was no difference in the rate of cell death between mutant and normal embryos until 6.75 days. This suggests that arrest in division accounts for the elevated mitotic index in mutants. A small region of the epiblast (proliferative zone) in mutant embryos is free of the mitotic abnormalities characteristic of the tissue as a whole. It is suggested that some of the ectoderm of the later embryos is produced from this region. (13 refs)

- 79-1792 Participation of Cultured Teratocarcinoma Cells in Mouse Embryogenesis.** (Eng) Papaioannou, V. E. (Dept. Zoology, Oxford Univ., South Parks Road, Oxford, OX1 3PS, England); Gardner, R. L.; McBurney, M. W.; Babinet, C.; Evans, M. J. *J Embryol Exp Morphol* 44: 93-104; 1978.

The fate of embryonal carcinoma cells from four in vitro cell lines was studied following microsurgical injection of the cells into genetically dissimilar AG/Cam mouse blastocysts. The blastocysts were allowed to develop to term, and the offspring were analyzed for chimerism using coat color markers and isozyme differences in glucose phosphate isomerase. When injected into blastocysts, cell line C86 produced tumors in 6/74 offspring. The tumors, which were detected at birth, were poorly differentiated neuroectodermal teratocarcinomas. The injection of cell line C17 produced 13 chimeras in 77 offspring. Five showed chimerism only in normal tissues, mainly melanocytes of the coat and eye; the other eight chimeras developed tumors. Seven of these developed in adults and were mainly fibrosarcomas. Cell line SIKR-OSB resulted in 1 normal chimera among 44 mice born. Among 86 animals developing to term following injection of PCC3/A/1, there was 1 chimera with a small tumor and 3 normal chimeras. The levels of chimerism were usually low. In test breeding experiments, there was no evidence of germ line chimerism. It is also relevant that the four cell lines had abnormal karyotypes, as seen by G-banding, in spite of normal or near-normal chromosome numbers. This may put the cells at some disadvantage in the embryo or render them incapable of forming functional gametes. Another important factor for the incorporation of cells into the embryo is the difference in cell cycle times between the embryo and the injected cells. (18 refs)

- 79-1793 Organ Culture as an In Vitro Test for Tumorigenic Cells.** (Eng) O'Donnell, R. W. (George Washington Univ., Washington, DC, 20006). *Diss Abstr Int B* 39(8): 3685; 1979. (1 ref)

79-1794 Reciprocal Control of Membrane Permeability of Transformed Cultures of Mouse Cell Lines by External and Internal ATP. (Eng) Rozenfurt, E. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Heppel, L. A. *J Biol Chem* 254(3): 708-714; 1979.

The regulation of membrane permeability in transformed (3T6 and SV3T3) and untransformed (3T3) mouse cells by ATP was studied. External ATP applied to transformed cultures caused a rapid efflux of acid-soluble pools, as measured by labeling with ³H-uridine, ³H-adenosine, or ³H-deoxyglucose. The max effect was achieved with 0.5 mM ATP; 0.05 mM had little or no effect. Low concentrations of uncouplers, energy transfer inhibitors, or inhibitors of respiration caused a synergistic effect when combined with low concentrations of ATP, and a massive stimulation of efflux resulted. The synergistic effect was observed with a wide variety of inhibitors, all of which were able to lower the concentration of intracellular ATP. A good correlation existed between reduction in ATP levels by the inhibitors and the synergistic effect. The synergistic effect of the inhibitors was prevented by glucose, which interferes with the reduction of intracellular ATP. These inhibitors caused a small stimulation of efflux in untransformed 3T3 cells, but ATP had no effect and there was no synergism observed. Oligomycin alone caused an immediate and massive efflux of pools in 3T3 cells and was not inhibited by glucose; it appeared that this was an effect peculiar to this compound and not a general property of uncouplers and energy inhibitors. It is postulated that the formation of a channel allowing efflux of acid-soluble pools is somehow determined by the levels of both extracellular and intracellular ATP. This channel is sealed in transformed cultures at neutral pH by an energy-requiring mechanism. (33 refs)

79-1795 Active Synthesis of Collagen by Albumin-producing Liver Parenchymal Cell Clones in Culture. (Eng) Hata, R. (Dept. Tissue Physiology, Medical Res. Inst., Tokyo Medical and Dental Univ., Tokyo 101, Japan); Ninomiya, Y.; Nagai, Y.; Sakakibara, K.; Tsukada, Y. *Proc Jpn Acad Ser B* 54(7): 391-396; 1978.

Two albumin-producing rat liver parenchymal epithelial cell clones (BB and BC) synthesized collagen at a level comprising 1.1%-2.0% of the total proteins. This level was two to nine times higher than that produced by two transformed fibroblastic cell lines from mouse skin and rat lung, respectively. BB and BC synthesized types I, X, and Y collagen, but a transformed rat liver epithelial cell line synthesized only I and X. (18 refs)

79-1796 A Survey of Growth in Soft Agar and Cell Surface Properties as Markers for Transformation in Adult Rat Liver Epithelial-like Cell Cultures. (Eng) San, R. H. (British Columbia Cancer Res. Centre, Vancouver, British Columbia, Canada); Laspia, M. F.; Soiefer, A. I.

Maslansky, C. J.; Rice, J. M.; Williams, G. M. *Cancer Res* 39(3): 1026-1034; 1979.

Growth in soft agar and five cell membrane properties were evaluated as markers for transformation in nine normal adult rat liver (ARL) and four hepatocarcinoma continuous epithelial-like cell lines. Seven of the nine ARL lines did not produce tumors in nude mice, but two (ARL 6 and ARL 17) were tumorigenic. Hepatocarcinoma lines HTC, ND-HC1, and MH₁C₁ were tumorigenic, but RH35 was not. Growth in soft agar was a specific and sensitive marker for transformation, but high uptake of 2-deoxy-D-glucose was specific but not sensitive. Agglutination and hemadsorption mediated by concanavalin A, multinucleation in the presence of cytochalasin B, and the presence of Mg²⁺-dependent ATPase activity did not correlate with tumorigenicity or with the other markers. Some of the lines were found to be carrying an occult infection by *Mycoplasma hyorhinis*, a porcine organism. The infection did not affect any of the properties studied, including tumorigenicity in nude mice, and it was eliminated by passage of the infected cells through nude mice. (63 refs)

79-1797 Identification of Transformed Rat Liver Epithelial Cells in Cultures. (Eng) Iype, P. T. (Paterson Labs., Christie Hosp. and Holt Radium Inst., Manchester M20 9BX, England); Allen, T. D. *Cancer Lett* 6(1): 27-32; 1979.

The growth potential of normal rat liver cells, rat liver epithelial cells transformed in vitro (chemically or spontaneously), and cells from a malignant hepatoma induced chemically in vivo was investigated under various experimental conditions. The control cells failed to form colonies over a base layer of living parent cells, whereas the transformed cells formed distinct colonies. Contact with living normal liver cells was required for the growth inhibition of the untransformed cells, as normal cells did produce regular colonies over a base layer prefixed with glutaraldehyde. The hepatoma cells exhibited signs of invasion in vitro in that they formed distinct colonies, surrounded by a highly stained area, on the base layers of normal cells. The fact that some of the in vitro-transformed liver cells formed compact colonies in the live base layer indicates that although these cells are no longer under the proliferation control exerted by normal cells, they have not yet acquired invasiveness. The altered properties of hepatic cells during the early stages of transformation can be assessed by plating these cells over a living base layer of normal liver cells. This method is believed to score the premalignant (anchorage-dependent) and fully transformed (anchorage-independent) liver cells. (11 refs)

79-1798 Establishment of a Rat Hepatoma Cell Line Which Has Ornithine Carbamoyltransferase Activity and Grows Continuously in Arginine-derived Medium. (Eng) Niwa, A. (Dept. Microbiology, Dokkyo Univ. Sch.

Medicine, Mibu, Tochigi 321-02, Japan); Yamamoto, K.; Yasumura, Y. *J Cell Physiol* 98(1): 177-184; 1979.

An ornithine carbamoyltransferase (OCT)-positive subline was developed from an epithelial cell line (H4-II-E, derived from the Reuber hepatoma H35) that has no significant OCT activity, by a multistep procedure. H4-II-E cells were exposed to gradually increasing concentrations of 5-bromo-deoxyuridine and then adapted to grow in medium in which glutamic acid was substituted for glutamine. The adapted cells were cultured in arginine-deprived medium for several mo before cell colonies were observed. Thereafter, the cell colonies were transferred at 10-day intervals and grown continuously in arginine-deprived ornithine-supplemented medium for >2 yr. The growth of the cells was effectively controlled by varying the ornithine concentration between 0.03 and 1 mM. The population of attached cells and OCT activity per culture dish were nearly constant at 2 mg cell protein (5×10^6 cells) and 100 units (50 units/mg protein), respectively, for as long as the cultures were maintained. These patterns of growth and OCT activity were constant in subsequent subcultures. These may be the only serially cultivated cells that have significant levels of OCT activity and can be grown in ornithine-supplemented arginine-deficient media. (21 refs)

79-1799 Establishment and Characterization of Primary Human Pancreatic Carcinoma in Continuous Cell Culture and in Nude Mice. (Eng) Grant, A. G. (Dept. Surgery, St. George's Hosp. Medical Sch., Cranmer Terrace, London SW17 0RE, England); Duke, D.; Hermon-Taylor, J. *Br J Cancer* 39(2): 143-151; 1979.

A primary human pancreatic exocrine adenocarcinoma established in tissue culture and xenografts established in im-

mune-deficient nu/nu mice were characterized. The primary tumor cells grew as an epithelioid monolayer without fibroblast contamination; density-dependent inhibition of cell growth was not observed at confluence. The doubling time stabilized at 36 hr after the 11th passage. Approx 10%-15% of the total cell population was accounted for by cells floating free in suspension; <1% of these cells formed new colonies after reseeding. Evidence of tumor origin was provided by a modal chromosome number of 62. The tumorigenicity of the cells was indicated by growth on a confluent monolayer of early passage diploid fibroblasts and in soft agar, and as solid tumors in nude mice. No growth was obtained with floating cells or fibroblasts. Xenografts established from the cell line or directly from primary tumor tissue retained the histology of the original tumor upon serial transplantation. The tumor cell line and the xenografts lacked the normal human pancreatic digestive enzymes, but it did exhibit glucose-6-phosphate dehydrogenase, 6-phosphogluconate dehydrogenase, phosphoglucose isomerase, phosphoglucomutase, carbonic anhydrase, and alkaline phosphatase activities. (13 refs)

79-1800 Fibrorectosigmoidoscopy. Results in 476 Cases. (Fre) Lambert, R. (Centre d'Endoscopie, Pavillon H, Hopital E. Herriot, F 69374 Lyon Cedex 2, France); Olive, C.; Chabanon, M.; Chabanon, R. *Nouv Presse Med* 7(46): 4213-4215; 1978.

Four hundred and seventy-six patients with or without digestive symptoms were examined by a 60-cm fiber rectosigmoidoscope. Nontumorous lesions were found in 44 patients, tumors in 105 (125 adenomas and 31 carcinomas). Seventy-one tumors (50 adenomas and 21 carcinomas) were in the area accessible to rigid rectosigmoidoscopy (0-19 cm); the other 85 tumors were beyond this area. (4 refs)

LIBRARY U. OF I. URBANA - CHAMPAIGN

Subject Index

Abnormalities

- Nephroblastoma
- Twins, 79-1727

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-

- Ames Test
- Mutagenic Activity, 79-1359
- Anemia, Aplastic
- DNA Repair, 79-1495
- Ataxia Telangiectasia
- DNA Repair, 79-1495
- Dwarfism
- DNA Repair, 79-1494, 79-1495
- Fibroblasts
- DNA-Protein Cross-Links, 79-1355
- DNA Repair, 79-1493
- Lymphocytes
- Chromosome Aberrations, 79-1356
- DNA Repair, 79-1356, 79-1492
- Poly Adenosine Diphosphate Ribose, 79-1492
- Mutagenic Activity
- Azaguanine Resistance, 79-1359
- Hamster V79 Cells, 79-1359
- Ultraviolet Rays
- DNA Repair, 79-1495
- Xeroderma Pigmentosum
- DNA Repair, 79-1493, 79-1494

Acetamide, *N*-Fluoren-2-yl-

- Aryl Hydrocarbon Hydroxylases
- Metabolism, Mouse, Review, 79-1208
- Benzylamine, *N*-(2-Chloroethyl)-*N*-(1-methyl-2-phenoxyethyl)-
- Receptors, Adrenergic, 79-1353
- Bladder Neoplasms
- Carcinoma, 79-1354
- Paraffin, 79-1354
- Cell Transformation, Neoplastic
- Quantitation Method, 79-1446
- Cells, Cultured
- Cell Transformation, Neoplastic, 79-1438
- Ouabain Resistance, 79-1438
- Cholanthrene, 3-Methyl-
- DNA, Binding, 79-1352
- Enzyme Activation
- Liver, Rat, 79-1352
- Epinephrine
- Receptors, Adrenergic, 79-1353
- Epoxide Hydratases
- Microsomes, Liver, 79-1350
- Glutathione
- Metabolism, Mouse, Review, 79-1208
- Isoproterenol
- Receptors, Adrenergic, 79-1353
- Microsomes, Liver
- DNA, Binding, 79-1352
- Oxygenases
- DNA, Binding, 79-1352
- Enzyme Activation, 79-1352
- 2-Propanol, 1-(Isopropylamino)-3-(1-naphthoxy)-
- Receptors, Adrenergic, 79-1353
- Receptors, Adrenergic
- Glycogen Phosphorylase, 79-1353
- Liver, Rat, 79-1353
- UDP Glucuronosyltransferase

Acetamide, *N*-Fluoren-2-yl- (cont'd)

- Microsomes, Liver, 79-1350
- Virus, Rauscher Murine Leukemia
- Virus, Replication, 79-1438

Acetamide, *N*-(1-Hydroxy-9*H*-fluoren-2-yl)-

- Bladder Neoplasms
- Carcinoma, 79-1354

Acetamide, *N*-(3-Hydroxy-9*H*-fluoren-2-yl)-

- Bladder Neoplasms
- Carcinoma, 79-1354

Acetamide, Thio-

- Epoxide Hydratases
- Microsomes, Liver, 79-1350
- UDP Glucuronosyltransferase
- Microsomes, Liver, 79-1350

Acetanilide

- Cytochrome P-450
- Enzymatic Activity, 79-1440

Acetanilide, 4'-Hydroxy-

- Aryl Hydrocarbon Hydroxylases
- Metabolism, Mouse, Review, 79-1208
- Glutathione
- Metabolism, Mouse, Review, 79-1208

Acetic Acid, Cadmium Salt

- Cell Transformation, Neoplastic
- Cells, Cultured, 79-1313
- Transplacental Carcinogenesis
- Dose-Response Study, Hamster, 79-1313

Acetic Acid, ((Carboxymethylimino)bis(ethylenenitrilo))tetra-Plutonium

- Decorporation, Mouse Skeleton, 79-1315

Acetic Acid, ((4-Chloro-*o*-tolyl)oxy)-

- DNA Replication
- Testis, Rat, 79-1351

Acetic Acid, (2,4-Dichlorophenoxy)-

- DNA Replication
- Testis, Rat, 79-1351
- Sarcoma, Reticulum Cell
- Occupational Hazard, 79-1776

Acetic Acid, *S*-2-(3,4-Dichlorothiophenyl)-

- Ether, Bis(2-Chloroethyl)-
- Urinary Metabolite, 79-1324
- Ethylene, Chloro-
- Urinary Metabolite, 79-1324

Acetic Acid, (Ethylenebis(oxyethylenenitrilo))tetra-

- Methanesulfonic Acid, Methyl Ester
- Thioguanine Resistance, 79-1319

Acetic Acid, (Ethylenedinitrilo)tetra-

- Methanesulfonic Acid, Methyl Ester
- Thioguanine Resistance, 79-1319

Acetic Acid, (2,4,5-Trichlorophenoxy)-

- DNA Replication
- Testis, Rat, 79-1351
- Mesenchymoma
- Carcinogenic Potential, Review, 79-1225
- Sarcoma, Reticulum Cell
- Occupational Hazard, 79-1776

- Acetic Acid, (2,4,5-Trichlorophenoxy)-, Isooctyl Ester**
DNA Replication
Testis, Rat, 79-1351
- Acetohydroxamic Acid, *N*-Fluoren-2-yl-**
Bladder Neoplasms
Carcinoma, 79-1354
- p*-Acetophenetidine**
Bladder Neoplasms
Drugs, Review, 79-1293
- Acetylglucosaminidase**
Colonic Neoplasms
Hydrazine, 1,2-Dimethyl-, 79-1348
- Acridine, 3,6-Diamino-**
Acridine, 3,6-Diamino-2,7-dimethyl-
Photomutagenic Activity, 79-1509
Fluorescence
Photomutagenic Activity, 79-1509
Virus, SV40
Photodynamic Induction, 79-1629
- Acridine, 3,6-Diamino-2,7-dimethyl-**
Acridine, 3,6-Diamino-
Photomutagenic Activity, 79-1509
Escherichia coli
Photomutagenic Activity, 79-1509
Fluorescence
Photomutagenic Activity, 79-1509
Methylene Blue
Photomutagenic Activity, 79-1509
Quinacrine Hydrochloride
Photomutagenic Activity, 79-1509
- Acridine Mustard**
Dwarfism
DNA Repair, 79-1494
Xeroderma Pigmentosum
DNA Repair, 79-1494
- Actin**
Burkitt's Lymphoma
B-Lymphocytes, 79-1688
B-Lymphocytes
Plant Agglutinins, 79-1688
Virus, Epstein-Barr
B-Lymphocytes, 79-1688

 Cytochrome P-450
 Barbituric Acid, 5-Ethyl-5-phenyl-, 79-1458
- Benzo(a)pyrene, 7,8-Dihydroxy-9,10-oxy-7,8,9,10-tetrahydro-**
 DNA, Binding
 Stereoselectivity, 79-1449
- Benzo(a)pyrene-3,6-dione**
 Benzo(a)pyren-6-ol
 Enzyme Activation, 79-1452
- Benzo(a)pyrene 4,5-Oxide**
 Epoxide Hydratases
 Liver, Rat, 79-1473
- Benzo(b)triphenylene**
 Skin Neoplasms
 DNA, Binding, 79-1420
- Benzo(e)pyrene**
 Air Pollution
 Ames Test, 79-1466
 Concentration Levels, 79-1434
- 5,6-Benzoflavone**
 Aryl Hydrocarbon Hydroxylases
 Mammæ, Rat, 79-1472
 Benzo(a)pyrene
 Quinone Derivatives, 79-1455
 Dimethylamine, *N*-Nitroso-
 DNA, Binding, 79-1364
- 7,8-Benzoflavone**
 Aryl Hydrocarbon Hydroxylases
 Mammæ, Rat, 79-1472
 Microsomes, Liver, 79-1469
 Species Difference, 79-1469
- Benzo(a)pyrene**
 Metabolism, Fibroblasts, 79-1462
 Cholanthrene, 3-Methyl-
 Aryl Hydrocarbon Hydroxylases, 79-1469
 Cytochrome P-450, 79-1469
 Cytochrome P-450
 Microsomes, Liver, 79-1469
 Hydroxylases
 Microsomes, Liver, 79-1469
 Species Difference, 79-1469
- Benzoic Acid, *p*-Amino-**
 Ultraviolet Rays
 DNA Repair, 79-1496
- Benzoic Acid, 4-(Dimethylamino)-, Pentyl Ester**
 Ultraviolet Rays
 DNA Repair, 79-1496
- Benzoic Acid, *p*-Hydroxymercuri-**
 Colonic Neoplasms
 Hexosaminidases, 79-1348
- Benzylamine**
 Dimethylamine, *N*-Nitroso-
 DNA, Binding, 79-1364
- Benzylamine, *N*-(2-Chloroethyl)-*N*-(1-methyl-2-phenoxyethyl)-**
 Acetamide, *N*-Fluoren-2-yl-
 Receptors, Adrenergic, 79-1353
- Beta 2 Microglobulin**
 Virus, Herpes Simplex
 B-Lymphocytes, 79-1636
 T-Lymphocytes, 79-1636
- Bile**
 2,5-Hexadienoic Acid, 3-Methoxy-5-methyl-4-oxo-
 Metabolism, Rat, 79-1384
- Bile Acids and Salts**
 Lipids
 Diet, 79-1784
 Enterohepatic Circulation, 79-1784

Bile Acids and Salts (cont'd)

Metabolism, Rat, 79-1784

Biotin

Cell Transformation, Neoplastic
Growth Substances, 79-1617

Biphenyl

Benzene, 4-Allyl-1,2-(methylenedioxy)-
Hydroxylation, 79-1390
Cholanthrene, 3-Methyl-
Hydroxylation, 79-1390
Triazene, 3,3-Dimethyl-1-*p*-(bromophenyl)-
Hydroxylation, 79-1390
Triazene, 3,3-Dimethyl-1-*p*-(chlorophenyl)-
Hydroxylation, 79-1390
Triazene, 3,3-Dimethyl-1-phenyl-
Hydroxylation, 79-1390
Triazene, 3,3-Dimethyl-1-(2,4,6-tribromophenyl)-
Hydroxylation, 79-1390
Triazene, 3,3-Dimethyl-1-(2,4,6-trichlorophenyl)-
Hydroxylation, 79-1390
Triazene, 3-Methyl-1-(2,4,6-tribromomethyl)-
Hydroxylation, 79-1390
Triazene, 3-Methyl-1-(2,4,6-trichlorophenyl)-
Hydroxylation, 79-1390
Triazene, 3-Monomethyl-1-phenyl-
Hydroxylation, 79-1390

Biphenyl, Decabromo-

Carcinogenic Potential

- Virus, Murine Mammary Tumor
 - Virus Replication, 79-1561

Cell Adhesion

- Virus, Rous Sarcoma
 - Temperature Sensitive Mutants, 79-1542

Cell Aggregation

- Virus, Polyoma
 - Cell Transformation, Neoplastic, 79-1553
 - Hexanoic Acid, 6-Amino-, 79-1553
 - LETS Protein, 79-1553
 - Trypsin, 79-1553
- Virus, Rous Sarcoma
 - Cell Transformation, Neoplastic, 79-1553
 - Hexanoic Acid, 6-Amino-, 79-1553
 - LETS Protein, 79-1553
 - Trypsin, 79-1553

Cell Differentiation

- Aldosterone

Cell Differentiation (cont'd)

- Mammas, 79-1485
- Erythroleukemia
 - Granulocytes, 79-1696
- Estradiol
 - Mammas, 79-1485
- Insulin
 - Mammas, 79-1485
- Melanoma
 - Hybrid Cells, 79-1785
- Mitosis
 - Embryo, Mouse, 79-1791
- Mutation
 - Embryo, Mouse, 79-1791
- Paraproteinemia
 - Transplantation, Homologous, 79-1684
- Progesterone
 - Mammas, 79-1485
- Prolactin
 - Mammas, 79-1485
- 4,4'-Stilbenediol, α, α' -Diethyl-
 - Estrus, 79-1481
 - Vagina, Mouse, 79-1481
- Teratoid Tumor
 - Cells, Cultured, 79-1792
 - Chimera, Mouse, 79-1792
 - Melanocytes, 79-1792
- Testosterone
 - Mammas, 79-1485
- 12-*O*-Tetradecanoylphorbol-13-acetate
 - Chick Embryo, 79-1428
 - Muscles, 79-1428
- Thyroxine
 - Mammas, 79-1485

Cell Division

- α -Amanitin
 - Cell Cycle Kinetics, 79-1780
- Methanesulfonic Acid, Methyl Ester
 - Thioguanine Resistance, 79-1319
- Peptides
 - Cell Cycle Kinetics, 79-1780
- 12-*O*-Tetradecanoylphorbol-13-acetate
 - Cell Cycle Kinetics, 79-1780

Cell Membrane

- Cell Transformation, Neoplastic
 - Surface Properties, 79-1796
- 12-*O*-Tetradecanoylphorbol-13-acetate
 - Chick Embryo, 79-1428
- Virus, Epstein-Barr
 - Antigen-Antibody Reactions, 79-1645
 - Antigens, Viral, 79-1641
- Virus, Hamster Sarcoma
 - Glycoproteins, 79-1594
- Virus, Rauscher Murine Leukemia
 - Glycoproteins, 79-1583, 79-1584, 79-1586
 - Histocompatibility Antigens, 79-1584
- Virus, Rous Sarcoma
 - Cell Transformation, Neoplastic, 79-1552
- Virus, SV40
 - Antigens, Viral, 79-1610

Cell Membrane Permeability

- Adenosine Triphosphatase
 - Cell Transformation, Neoplastic, 79-1794
 - Cells, Cultured, 79-1794
 - Enzyme Inhibitors, 79-1794
- Virus, SV40

Cell Membrane Permeability (cont'd)

- Adenosine Triphosphatase, 79-1794

Cell Transformation, Neoplastic

- Acetamide, *N*-Fluorenyl-2-yl-
 - Cells, Cultured, 79-1438
 - Quantitation Method, 79-1446
- Acetic Acid, Cadmium Salt
 - Cells, Cultured, 79-1313
- Adenomatosis, Familial Endocrine
 - Virus, RNA Tumor, 79-1257
- Adenosine Cyclic 3',5' Monophosphate
 - Cell Cycle Kinetics, 79-1781
 - Membrane Phosphorylation, 79-1781
- Adenosine Triphosphatase
 - Cell Membrane Permeability, 79-1794
 - Glucose, 79-1794
 - Oligomycin, 79-1794
- Aflatoxin B1
 - Age Factors, 79-1344
 - Fibroblasts, 79-1344
- Antigens, Neoplasms

DNA Repair

- Case Report, Complementation Group, 79-1711

Fibroblasts

- DNA Repair, 79-1494

Methanesulfonic Acid, Ethyl Ester

- DNA Repair, 79-1494

Quinoline, 4-Nitro-, 1-Oxide

- DNA Repair, 79-1494

Ultraviolet Rays

- DNA Repair, 79-1493, 79-1494

Zinc, (Ethylenebis(dithiocarbamate))-

- Ethanol, 2-((2-Aminoethyl)amino)-
 - Carcinogen Residues, 79-1320
- Plasmopara viticola*, 79-1320
- 2-Imidazolidinethione
 - Carcinogen Residues, 79-1320

Zineb

- see* Zinc, (Ethylenebis(dithiocarbamate))-

Zollinger-Ellison Syndrome

- Diarrhea
 - Diagnosis, Review, 79-1201

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index, is \$90.00 U.S., Canada and Mexico and \$120.00 foreign. Individual issues will be charged at \$10.00 to subscribers, \$15.00 each to non-subscribers. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

LIBRARY U. OF I. URBANA - CHAMPAIGN

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)
ATP	adenosine triphosphate	ml	milliliter(s)

REVIEW

- 79-1801 Differentiation of Normal and Neoplastic Hematopoietic Cells: A Summary.** (Eng) Clarkson, B. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY, 10021). *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 953-967; 1978.

Recent developments in various fields related to the differentiation of normal and neoplastic hematopoietic cells are summarized. Topics discussed include: ontogeny of hematopoietic development, attempts to isolate hematopoietic stem cells and define their properties, genetic control of antigenic expression of normal and transformed cells, regulation of hematopoietic differentiation, influence of viruses on transformation and differentiation, clinicopathological pathways, the development and integration of the immune system, and the use of newly recognized cell markers for defining the origins and abnormalities of specific cell types involved in various hematopoietic diseases. The interrelatedness of different research areas is emphasized. (no refs)

- 79-1802 Erythroleukemia Cells: Commitment to Differentiate the Role of the Cell Surface.** (Eng) Rifkind, R. A. (Cancer Center, Columbia Univ. Coll. Physicians and Surgeons, New York, NY, 10032); Fibach, E.; Reuben, R. C.; Gazitt, Y.; Yamasaki, H.; Weinstein, I. B.; Nudel, U.; Sumida, I.; Terada, M.; Marks, P. A. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 209-220; 1978.

Evidence indicating there are two components to induced differentiation, the commitment of murine erythroleukemia cells (MELC) to erythropoietic differentiation and the program that coordinates the series of biosynthetic and morphogenetic events that constitute the actual expression of the erythropoietic developmental process, is reviewed, along with evidence indicating that alterations of the plasma membrane may be implicated in the induction of differentiation by some agents. Commitment was responsive to the concentration of hexamethylene bisacetamide (HMBA), but expression was not. When MELC were exposed continuously to HMBA, benzidine-reactive, Hb-containing cells were detectable in the culture after 48 hr. When MELC were suspended in HMBA for various times (5-100 hr) and transferred to a fresh medium free of HMBA, commitment was detected after 24 hr. When MELC were cultured with HMBA and transferred to inducer-free semisolid media, commitment was detected at 12-16 hr. The number of cells in the colony was related to the proportion of benzidine-reactive cells in the colony. MELC strains D519 and DR10 had an increased cyclic AMP content when exposed to certain inducing agents, implicating

plasma membrane or plasma membrane-related functions in commitment. To determine the relationship between 12-O-tetradecanoylphorbol-13-acetate (TPA)-mediated inhibition of differentiation and commitment to differentiation, TPA was added to MELC at various times after the addition of HMBA. Max inhibition of differentiation occurred even when TPA was added up to 24 hr after HMBA, suggesting that TPA can only inhibit differentiation of cells that have not yet passed a critical step related to commitment. Thus, a wide variety of agents can alter significantly the probability for commitment to and expression of the program of erythropoietic differentiation in MELC. Some agents may have a primary effect at the plasma membrane level. The unique properties of the individual inducing agents may reflect various potential sites of interaction between inducing agents and the sequential steps of the common pathway for the regulation of erythropoietic differentiation. (45 refs)

- 79-1803 Biology of the Human Malignant Lymphomas. V. Differentiation and Neoplastic Properties of Established Lymphoma Cell Lines.** (Eng) Epstein, A. L. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Kaplan, H. S. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 915-934; 1978.

The maintenance of the differentiated state of malignant lymphoma cells established in vitro is reviewed, along with the neoplastic properties of these cells. Malignant lymphomas were grown on agar and multiple clones were isolated from individual cell lines. The clonal subpopulations maintained the differentiated traits of the parent cell lines; however, certain clones expressed specific receptors with increased frequencies, indicating that the genes responsible for these traits could be segregated by cloning techniques. The malignant cells continued to express normal differentiation antigens, surface receptors, and functional capabilities in vitro. Diffuse histiocytic and undifferentiated lymphoma cells initially had a cloning efficiency of <1% when 0.5% Noble agar was used as a substrate. In the presence of human serum and selected feeder monolayers, however, the cloning efficiencies increased to 15%-25%. Supplements such as dithiothreitol, 2-mercaptoethanol, and pleural effusion fluids produced concentration-dependent increases in cloning efficiency. For a given cell line, cells plated on the agar surface and in semisolid agar suspension had identical cloning efficiencies. The cloning efficiencies of individual cell lines increased from <1% to approx 50% after a single passage on agar. The applicability of experimental criteria for determining the malignant nature of cultured mammalian fibroblasts to malignant

cells of lymphoid tissue origin was assessed. The potential use of malignant lymphoma cells for clinical and basic biological research is considered. (109 refs)

- 79-1804 Potential of Plant Genetic Systems for Monitoring and Screening Mutagens.** (Eng) Nilan, R. A. (Program in Genetics, Washington State Univ., Pullman, WA, 99164). *Environ Health Perspect* 27: 181-196; 1978.

The scope and potential of plant genetic systems for mutagenesis research are reviewed. There are about a dozen reliable plant genetic systems that can increase the scope and effectiveness of chemical and physical mutagen screening and monitoring procedures. Major advantages of these systems relate to their reproductive nature, easy culture, and growth habits. Plants are the only systems now in use as monitors of genetic effects caused by air pollution and pesticides. (126 refs)

- 79-1805 Introduction: Utilization of Higher Plant Systems as Monitors of Environmental Mutagens.** (Eng) de Serres, F. J. (Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC, 27709). *Environ Health Perspect* 27: 3-6; 1978.

A workshop was organized to review the major problems in environmental mutagenesis, to provide illustrative examples of areas where various plant systems have already been put to use, and to identify additional approaches for research. The relationship between mutagenicity and carcinogenicity is illustrated by experience with 2-(2-furyl)-3-(5-nitro-2-furyl) acrylamide, a nitrofur derivative used as a food preservative in Japan. This chemical was found to be mutagenic in cultured bacterial, human, yeast, and *Neurospora* cells and to produce stomach cancer in mice. Investigations in the US, England, and Japan have shown that 90%-95% of chemical carcinogens are also mutagens. Research in environmental mutagenesis and genetic toxicology is divided into four main areas: basic mechanisms by which mutations are produced; development of assay systems that provide a comprehensive evaluation of chemicals in widespread use; environmental monitoring for mutagens; and evaluation of the risk of exposure to chemicals with identified potential in mass screening programs. Plant systems seem especially well-suited for research in at least the first three areas. The most promising areas for future development are plant screening tests for nondisjunction and for the evaluation of air and water pollutants. In the latter category, the *Tradescantia* stamen hair system is being used to evaluate the mutagenicity of various air pollutants. (9 refs)

- 79-1806 Mutagenicity and Water Chlorination: Prospect and Perspective.** (Eng) Cumming, R. B. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830). *Water Chlorination* 2: 411-416; 1978.

A brief overview of mutagenicity and mutagenicity testing as they are perceived today is presented, and their relevance to assessment of the impact of water chlorination on public health is shown. (6 refs)

- 79-1807 Microsomal Aspects of Carcinogenesis and Neoplasia.** (Eng) Apffel, C. A. (Ira T. Nathan-son Res. Labs., Pondville Hosp., Walpole, MA, 02081). *Med Hypotheses* 5(1): 23-52; 1979.

Microsomal aspects of carcinogenesis and neoplasia are reviewed. Carcinogenic agents initiate biophysical perturbations, chemical alterations, and conformational transitions in the membrane lattice of the endoplasmic reticulum (ER). Crucial among the malignancy-related alterations is the increased, irreversible detachment of polysomes from membranes of the rough ER. Since only attached polysomes can synthesize microsomal cytochromes, the values of these factors are decreased and mixed function oxidase activities are impaired in tumor cells that possess a monooxygenase system before malignant transformation. Consequences more broadly common to tumor cells of different categories are uncontrolled biosynthesis of cholesterol and derepressed thiol-disulfide exchange with subsequently activated synthesis of nonspecific proteins and of DNA involved in neoplastic growth. Apparently, the initial carcinogenic event destroys proteins required for polysome anchoring. As in the case of cytochrome P-450 and b5, only membrane-bound polysomes may be capable of synthesizing the attachment proteins. The destruction of the attachment sites (proteins), therefore, implies a vertical transmission of the membrane-polysome dieresis with ensuing uncontrolled growth through successive generations of cells. No permanent alteration of genetic material has to be postulated. (150 refs)

- 79-1808 Role of Biotransformation in the Toxicity of Inhalation Anesthetics.** (Eng) Vaughan, R. W. (Dept. Anesthesiology, Univ. Arizona, Coll. Medicine, Tucson, AZ, 85724); Sipes, I. G.; Brown, B. R. *Life Sci* 23(25): 2447-2462; 1979.

Subacute and chronic viscerotoxicity due to inhalation anesthetics are reviewed. The anesthetics considered are chloroform, trichloroethylene, fluroxene, methoxyflurane, halothane, enflurane, and isoflurane. Abundant evidence relates the bioactivation of xenobiotics, including these anesthetics, to highly reactive intermediates. These intermediates covalently interact with tissue macromolecules and thus alter the integrity of cells. These alterations can lead to necrosis, hypertrophy, or carcinogenesis. The interaction of a xenobiotic with DNA may predict the carcinogenic potential of the compound. This is particularly important when an individual

is subject to continuous exposures of trace amounts of the chemical. Various factors, such as excess ethanol intake or the use of drugs that induce the microsomal drug-metabolizing enzymes, may modify the biotransformation of anesthetic agents and thus increase the risk of a potential interaction with DNA. These findings indicate that it is important to know to what extent anesthetic agents undergo bioactivation and the fate of the reactive intermediates that are produced. The widespread use of these drugs in clinical anesthetic practice dictates continued intense studies. (123 refs)

- 79-1809 The Drinking Water-Cancer-Carbon Filtration Problem.** (Eng) Hyman, E. S. (3629 Prytania St., New Orleans, LA, 70115). *J La State Med Soc* 131(1): 11-32; 1979.

Information opposing the hypothesis that drinking water in the US causes cancer is presented in response to public concern about chloroform levels in New Orleans' drinking water. It is suggested that chloroform per se or as a surrogate for other halogenated organics is low on the list of potential carcinogens, especially in comparison with cigarette smoke, inhaled asbestos, or nitrosamines produced by nitrates in food. It is doubtful whether chloroform can cause cancer in rats or any other species without first destroying biochemical processes essential to the survival of most of the liver cells and overwhelming the metabolic pathways that rid the body of that agent. It is also suggested that statistical studies showing correlations between river water or chloroform and cancer are not convincing. (72 refs)

- 79-1810 Potential Halogenated Industrial Carcinogenic and Mutagenic Chemicals. I. Halogenated Unsaturated Hydrocarbons.** (Eng) Fishbein, L. (National Center Toxicological Res., Jefferson, AR, 72079). *Sci Total Environ* 11(2): 111-161; 1979.

Data on the carcinogenicity and mutagenicity of several of the most industrially significant halogenated unsaturated hydrocarbons are reviewed to assess the nature of their present potential risk. These compounds are vinyl chloride, vinylidene chloride, trichloroethylene, perchloroethylene, chloroprene, trans-1,4-dichlorobutene, hexachlorobutadiene, and allyl chloride. Aspects of their synthesis (primarily in terms of the nature of possible hazardous trace impurities), production volumes and use patterns, chemical and biological reactivity and stability, environmental occurrence, and national permissible worker exposure levels are considered. Experimental and human epidemiologic evidence of the carcinogenicity and mutagenicity of the hydrocarbons is reviewed, as are data concerning their in vivo and in vitro metabolism. (302 refs)

- 79-1811 Potential Halogenated Industrial Carcinogenic and Mutagenic Chemicals II. Halogenated Saturated Hydrocarbons.** (Eng) Fishbein, L. (Natl. Center for Toxicological Res., Jefferson, AR, 72079). *Sci Total Environ* 11(2): 163-195; 1979.

The carcinogenic and mutagenic potentials of the industrially significant halogenated saturated hydrocarbons are reviewed. These compounds possess considerable utility as solvents, drycleaning fluids, refrigerants, fumigants, degreasing agents, propellants, and intermediates in the production of other chemicals, textiles, and plastics. They include methyl chloride, methylene chloride, chloroform, carbon tetrachloride, methyl chloroform, 1,1,2-trichloroethane, hexachloroethane, ethyl chloride, and the fluorocarbons. They are discussed principally in terms of their synthesis or occurrence, areas of application, stability, distribution, reactivity, exposure levels, populations at risk, carcinogenicity, mutagenicity, and metabolism. (164 refs)

- 79-1812 Manufacturing Processes. Refining of Nickel.** (Eng) Morgan, L. G. (Medical Dept., Inco Europe Ltd., Clydach, Swansea SA6 5QR, Wales). *J Soc Occup Med* 29(1): 33-35; 1979.

Health hazards associated with processes used in refining sulfide and lateritic nickel ores are described briefly. Respiratory cancer has been associated with dusty processes in nickel refining, but this hazard has been eliminated. Nickel carbonyl gas is highly toxic; it is normally found only when nickel is refined by the carbonyl process. The gas has caused respiratory cancer in experimental animals, but there is no evidence that this is the case in humans. (4 refs)

- 79-1813 Dietary Polyunsaturated Fat Versus Saturated Fat in Relation to Mammary Carcinogenesis.** (Eng) Carroll, K. K. (Dept. Biochemistry, Univ. Western Ontario, London, Ontario, Canada, N6A 5C1); Hopkins, G. J. *Lipids* 14(2): 155-158; 1979.

The relationship between dietary fat and mammary carcinogenesis is reviewed. Experiments in rats and mice showed that animals fed high-fat diets were more susceptible to spontaneous and carcinogen-induced mammary tumors than those fed low-fat diets. Apparently, dietary fat acted as a promoter rather than an initiator of tumors. Unsaturated fats enhanced mammary tumorigenesis to a greater extent than did saturated fats, although there was no direct correlation between degree of unsaturation and mammary tumor yield. Breast cancer mortality among humans in different countries showed a positive correlation with total fat intake, a somewhat smaller positive correlation with animal fat intake, and no correlation with vegetable fat intake. The fact that Japanese women consume a more unsaturated type of fat than Americans but have a lower incidence of breast cancer fits in with experi-

mental data showing a requirement for polyunsaturated oil in mammary tumorigenesis that is not satisfied by fats such as coconut oil or beef tallow but is satisfied by adding 3% sunflower seed oil to these fats. There is an overall requirement for a high-fat diet in addition to the polyunsaturated fat. Most human diets probably supply sufficient polyunsaturated fat to achieve the promoting effect in the animal model. It should be possible to reduce breast cancer incidence and mortality by reducing the intake of meat, milk products, margarines, shortenings, and salad oils. (21 refs)

- 79-1814 Drug Interactions in the Intestinal Tract.** (Ger) Mitznegg, P. (Institut für Pharmakologie und Toxikologie, Universität Erlangen-Nürnberg, Universitätsstrasse 22, 8520 Erlangen, W. Germany). *Fortschr Med* 97(8): 315-317; 1979.

Mechanisms of drug interactions in the gastrointestinal tract are reviewed briefly. The combination of paraffin-containing laxatives and the emulsifier sodium dioctyl sulfosuccinate (sometimes present in laxatives) should be avoided, as it may lead to the formation of foreign-body granulomas with possible subsequent degeneration to malignancy. (5 refs)

- 79-1815 Experimental Colon Carcinogenesis.** (Eng) Zedek, M. S. (Lab. Pharmacology, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021). *Gastrointest Tract Cancer* 343-360; 1978.

Studies of the sensitivity of colonic epithelium to the induction of tumors by methylazoxymethanol (MAM), dimethylhydrazine (DMH), azoxymethane (AOM), N-methyl-N'-nitronitrosoguanidine (MNNG), or N-methyl-N-nitrosourea (MNU) are reviewed, along with evidence of the role of dietary factors, intestinal flora, and bile acids in colon cancer induction. The common feature of the colon carcinogens (CCG) is the eventual formation of a methylating moiety. However, slight modification of the structure of these compounds results in compounds that cannot be activated to CCG. CCG are effectively transported to their target sites via the circulation. They do not require transport by the bile or metabolism by intestinal flora to exert their biological effects. Several findings indicate that the target tissues directly convert the parent compounds into ultimate carcinogens. The fact that a single treatment with MAM acetate induces more tumors of the colon than of the duodenum or cecum, even though DNA synthesis in each of these tissues is inhibited similarly, suggests that other factors play a modifying role in tumor development. In this regard, several investigations indicate that bile acids and/or bacteria may influence colon tumor formation. The finding that small intestine and colon respond similarly to the toxic effects of 5-fluorouracil and nitrogen mustard exaggerates even further the selective resistance of jejunum and ileum to the carcinogen-induced lesions. Relationships found between age and sensitivity to tumor in-

duction may prove significant in view of the suggestion that metabolic processes, the activity of which may be age-related, may enhance the degradation of MAM to its ultimate carcinogenic form. It has been shown that CCG can interact with nucleic acids and that DNA strand breakage can occur and, in some cases, persist for prolonged periods. Information regarding the mechanism of cell detachment at the mucosal surface of the intestine and the effects of CCG on this process may prove useful in understanding polyp formation. (85 refs)

- 79-1816 Unit of Environmental Carcinogens.** (Eng) Griciute, L. (International Agency Res. Cancer, Lyon, France). *IARC Annual Report* 44-65; 1978.

The 1978 activities of the Unit of Environmental Carcinogens of the International Agency for Research on Cancer are reported. The unit is continuing to elaborate and standardize techniques for analyzing environmental carcinogens and to measure these substances in environmental samples. A collaborative study is being made of methods for analyzing volatile and nonvolatile N-nitrosamines (NA's) and an aflatoxin sample check survey was started. Various environmental samples (alcoholic beverages, experimental animal feed, urine samples in areas with endemic urinary bladder cancer, tobacco smoke, pharmaceutical formulations, and bread) are being analyzed for NA's and other chemical carcinogens. *In vivo* formation of NA's was studied in the laboratory, by investigating the role of phenols in nitrosation, and in the field, by determining nitrite levels in salivas of the population of the Caspian littoral with differing esophageal cancer morbidity. Collaborative studies of the relation between asbestos and cancer and of the combined action of benzo(a)pyrene, N-nitrosodiethylamine, and aflatoxin B₁ at low, marginally active doses are being conducted. The latter study is designed to elucidate the behavior of several chemicals in the same environmental sample. Carcinogenicity testing of the antileprosy drug dapsone in rats and mice revealed that dapsone is slightly carcinogenic in these rodents. Fibrosarcomas and angiosarcomas of the spleen were seen in rats, mostly in males, along with cancers of the thyroid. Hemangiosarcomas of the liver were noted in mice. The tumors occurred during the second year of the experiment. (19 refs)

- 79-1817 Unit of Chemical Carcinogenesis.** (Eng) Tomatis, L. (International Agency Res. Cancer, Lyon, France). *IARC Annual Report* 77-113; 1978.

The activities of the Unit of Chemical Carcinogenesis of the International Agency for Research on Cancer (IARC) continue to be concerned with identifying potentially carcinogenic chemicals in the environment and evaluating their risk to humans, and developing criteria for better assessment of the significance of experimental results in predicting similar effects in humans. A detailed summary of these activities by various investigators is given. Up to September 1978, 19

volumes of IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans have been published. A total of 420 chemicals have been evaluated. Evidence or a strong suspicion of a causal association with cancer in humans was found for 26 chemicals; for a further 19 chemicals, no evaluation of a carcinogenic risk to humans was made since the available data were inconclusive. These chemicals are tabulated, along with chemicals for which there is sufficient evidence of carcinogenicity in experimental animals. The general paucity of epidemiological studies and inadequacies in several experimental reports were among the greatest difficulties encountered during compilation of the monographs. Criteria for carrying out and reporting long and short-term carcinogenicity experiments and related tests are being drafted to make published results universally acceptable. A worldwide survey of chemicals being tested for carcinogenicity is being continued, with the aims of avoiding unnecessary duplication of research, of increasing communication among scientists, and of making a census of available research facilities and of the chemicals being tested. (64 refs)

- 79-1818 Cocarcinogenesis.** (Eng) Sivak, A. (Biomedical Sciences Section, Arthur D. Little, Inc., Cambridge, MA, 02140). *Biochim Biophys Acta* 560(1): 67-89; 1979.

The role of exogenous chemical agents, viruses, the immune system, nutritional factors, and hormones as cocarcinogens in animals and humans is reviewed. Cocarcinogenic (CC) effects of exogenous chemicals have been demonstrated in mouse skin, rat liver, rat and dog bladder, rat gastrointestinal tract, and mouse and hamster lung. The discovery of excess deaths from lung cancer among uranium miners who are also cigarette smokers suggests a CC effect. Cell culture systems have been developed to demonstrate tumor promotion, a special case of CC. RNA tumor viruses are CC with 3-methylcholanthrene in mice. Hepatitis B virus appears to be involved, along with other factors, in human hepatic carcinoma, especially in tropical Asia and Africa. Nasal instillation of influenza virus has a CC influence in the mouse lung with inhalation of a polycyclic aromatic hydrocarbon aerosol or diethylnitrosamine in the drinking water. No clear explanation has been found for the tumor-enhancing or CC effect of immune system reactions, but it appears to be the result of a low-level immune response. Suboptimal levels of even a single nutrient may have a strong influence on tumor induction by a carcinogen. In animal systems and clinical situations, the growth of mammary and prostate tumors can be modulated by hormone treatment. Although CC has been demonstrated repeatedly, the specific cellular and biochemical processes involved are poorly understood. (182 refs)

- 79-1819 Experimental Carcinogenesis of Antitumour Drugs.** (Eng) Schmahl, D. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Neuenheimer

Feld 280, D-6900 Heidelberg, W. Germany); Habs, M. *Cancer Treat Rev* 5(4): 175-184; 1978.

The carcinogenic potential of anticancer chemotherapeutic agents is reviewed. These drugs have been evaluated in mice, rats, monkeys and hamsters. Alkylating agents, including 5-(3,3-dimethyl-1-triazeno)imidazole-4-carboxamide, uracil mustard, procarbazine, and cyclophosphamide, have a relatively strong carcinogenic action, as do the nitrosoureas. However, nitrosourea analogs with good antitumor activity and reduced carcinogenicity (eg, 1-(2-hydroxyethyl)-3-(2-chloroethyl)-3-nitrosourea) also exist. Although studies of the carcinogenicity of antimetabolites and antimitotic agents have produced contradictory results, these compounds appear to be less carcinogenic than the alkylating agents. Among the carcinostatic antibiotics, strong carcinogenic effects have been reported for adriamycin, rubidomycin, daunomycin, and mitomycin C. Combinations of anticancer drugs appear to be less carcinogenic than the same drugs individually. The induction times of the tumors induced by anticancer drugs are dose-dependent, and the organs affected may be specific (bladder cancer is caused by low doses of cyclophosphamide) or nonspecific (alkylating agents induce cancer in various organs). (63 refs)

- 79-1820 Camphor USP.** (Eng) Opdyke, D. L. (Res. Inst. Fragrance Materials, Inc., Englewood Cliffs, NJ, 07632). *Food Cosmet Toxicol* 16(Suppl 1): 665-671; 1978.

The structure, occurrence, preparation, and commercial uses of camphor are reviewed, and biological data concerning toxicity, inhalation effects, irritation, sensitization, metabolism, carcinogenicity, cytotoxicity, phytotoxicity, pharmacology, and effects on invertebrates are presented. The results of studies in which camphor was applied topically or injected ip in mice suggest that it is noncarcinogenic. (133 refs)

- 79-1821 Standards Corner.** (Eng) Anonymous (NIO-SH, Parklawn Bldg., 5600 Fishers Lane, Rockville, MD, 20852). *Occup Hazards* 41(2): 71-74; 1979.

The National Institute for Occupational Safety and Health (NIOSH) has issued a criteria document to the Occupational Safety and Health Administration warning that the dyestuff o-toluidine be kept below a ceiling concentration of $20 \mu\text{g}/\text{m}^3$ of air over a 60-min sampling period, that skin contact with the chemical be minimized, and that stringent engineering controls and controlled entry into areas where o-toluidine is handled or stored be enforced. o-Toluidine is an analog of benzidine. Both compounds have been shown to cause cancer in various organs of laboratory animals. In addition, epidemiological studies showed that workers who had been exposed to both compounds developed bladder cancer. NIOSH has also published a warning of the possible adverse effects of glycidyl ethers on the testes and blood-forming system and

has recommended that worker exposures to a group of diisocyanate monomers be limited. Epichlorohydrin has been identified by NIOSH as a potential human carcinogen, and it has been recommended that worker exposure to it be minimized and skin contact avoided. (no refs)

79-1822 The Stilbestrol Problem--Chairman's Report.

(Eng) Mattingly, R. F. (Dept. Gynecology and Obstetrics, Medical Coll. Wisconsin, 8700 W. Wisconsin Ave., Milwaukee, WI, 53226). In: *Cervical Pathology and Colposcopy. Selected Papers from the Second World Congress of Cervical Pathology and Colposcopy held in Graz, Austria, 15-18 October 1975*. Burghardt, E.; Holzer, E.; Jordan, J. A., eds. (Stuttgart: Georg Thieme Publishers): 146 pp.; 85-87; 1978.

The relationship between intrauterine diethylstilbestrol exposure and development of vaginal adenosis is briefly reviewed. (no refs)

79-1823 Colposcopic and Histological Findings in Stilbestrol-exposed Women. (Eng) Stafl, A. (Dept. Gynecology and Obstetrics, Medical Coll. Wisconsin, 8700 W. Wisconsin Ave., Milwaukee, WI, 53226). In: *Cervical Pathology and Colposcopy. Selected Papers from the Second World Congress of Cervical Pathology and Colposcopy held in Graz, Austria, 15-18 October 1975*. Burghardt, E.; Holzer, E.; Jordan, J. A., eds. (Stuttgart: Georg Thieme Publishers): 146 pp.; pp. 82-85; 1978.

Colposcopic examination of 280 young women whose mothers received diethylstilbestrol (DES) during the first trimester of pregnancy revealed vaginal adenosis in 231. Examination of the latter revealed that 96% had an abnormal colposcopic lesion, an incidence that was significantly higher than the 8% incidence of abnormal colposcopic lesions on the cervix of girls who were not exposed to DES. The results of studies concerning the morphogenesis of cervical neoplasias are summarized. (no refs)

79-1824 Prolactin and Human Breast Cancer: A Review.

(Eng) Nagasawa, H. (Pharmacology Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan). *Eur J Cancer* 15(3): 267-279; 1979.

The relationship between human prolactin (hPRL) and breast cancer (BC) is reviewed. A positive correlation between age and hPRL in cystic breast disease has been shown, but, although disordered hPRL regulation has been found in women with BC, its significance in the etiology of BC is uncertain. hPRL secretion varies according to age, stage in the menstrual cycle, and pregnancy. Certain drugs, including estrogenic agents and rauwolfia derivatives, stimulate pituitary

hPRL secretion, but the connection between these drugs and BC is at best uncertain. Serum prolactin levels have been reported to vary with race and to be elevated in close relatives of BC patients, but other studies have not supported these findings. Similarly, the relationship between BC and hPRL in the breast fluid or breast cyst fluid remains to be investigated, as does the possible relationship between BC and the ability of hPRL to stimulate the secretion of dehydroepiandrosterone. Studies have found that some BC's are sensitive to hPRL, and the existence of hPRL receptors in human breast tissues has been hypothesized. Also, factors that decrease prolactin secretion (eg, L-dopa and hypophysectomy) have often brought about regression of BC. Further research is needed to establish unequivocally the role of hPRL in human BC. (126 refs)

79-1825 Estrogens During Menopause and the Risk of Endometrial Carcinoma. (Ger) Lachnit-Fixon, U. (Department fur Gynakologische Endokrinologie, Schering AG, Mullerstrasse 170-178, D-1000 Berlin 65, W. Germany). *Wien Klin Wochenschr* 91(4): 111-118; 1979.

Data on the association between estrogen therapy during menopause and the risk of endometrial carcinoma are reviewed. To date, animal studies and clinical observations indicate that estrogens should not be regarded as carcinogens that lead to the development of endometrial carcinoma. However, because of their proliferative action, they can promote the carcinogenicity of certain other agents in hormone-dependent tissues. Progestogens, on the other hand, are anti-proliferative and they impede the action of these agents. Retrospective studies recently published in the US have revived the question of whether the risk of carcinoma is increased by estrogen administration after menopause. The value of these studies is criticized on the grounds of methodological bias, diagnostic errors in the precancerous and early stages of endometrial carcinoma, and therapeutic protocols. In any event, estrogens should always be given cyclically and at the lowest possible doses. In women with known risk factors, estrogens should be combined with progestogens, as in a normal cycle. This two-phase therapy could constitute a generally applicable alternative to menopausal estrogen therapy in the future. (53 refs)

79-1826 Role of Estrogens in the Pathogenesis of Endometrial Adenocarcinoma. (Ita) Campagnoli, C. (II Clinica Ostetrica e Ginecologica, Universita di Torino, Turin, Italy); Chiara, G.; Gilli, V. *Minerva Med* 70(2): 97-111; 1979.

Studies of the role of estrogens in the pathogenesis of endometrial adenocarcinoma are reviewed. Hyperplasia and subsequent malignant transformation of the endometrium were observed in rabbits, mice, and rats during long-term estrogen treatment. Endometrial adenocarcinoma is most

likely to occur if long-term estrogen stimulation is not counterbalanced adequately by progesterone (unopposed estrogen action). In this sense, nulliparity, late menopause, obesity, polycystic ovaries, and hormone-producing ovarian tumors (ie, granulosa cell and theca cell tumors) are risk factors in endometrial adenocarcinoma. The low incidence of endometrial adenocarcinoma in Japanese women compared with Caucasians is believed to be due to a difference in hormonal homeostasis that is ascribable to environmental and dietary factors (lower fat and protein levels in the Japanese diet). (24 refs)

- 79-1827 Carcinogenic Hazards from Prenatal Exposure to Environmental Chemicals.** (Eng) Napalkov, N. P. (Petrov Res. Inst. Oncology, Leningrad, USSR). *Cancer Detect Prev* 2(1): 21-46; 1979.

Literature data on experimental transplacental carcinogenesis are reviewed. The most important finding from animal experiments is that exposure to even a single dose of a carcinogen during pregnancy can lead to tumor development in the offspring or to increased sensitivity of the offspring to subsequent exposure to carcinogens, with the effects being additive. A chemical may have a typical organotropic tumorigenic effect in adults that differs from that in offspring exposed in utero. The fetus is most sensitive to the carcinogenic effects of a chemical during the later periods of gestation, ie, the histogenesis stage; to its teratogenic effects during the organogenesis stage; and to its lethal effects during the early stages. Transplacental exposure to carcinogens can induce congenital defects and/or neoplastic growth in the offspring. These events are different consequences of the same exposure rather than subsequent stages of one process. The type of teratogenic and carcinogenic response depends on the species of the organism, the nature and dose of the chemical, and the stage of embryogenesis. The risk of tumor development in offspring exposed to a carcinogen in utero is also determined by passage of sufficient concentrations of a carcinogen or its active metabolites through the placental and embryonic membrane barrier. One of the characteristics of transplacental carcinogenesis is the frequent development of multiple primary tumors. Several observations in rats, hamsters, and mice are in agreement with the field origin theory of multicentric tumor growth; ie, an entire tissue system or a large portion of it is considered a single tumor field. (59 refs)

- 79-1828 Environmental Carcinogenesis.** (Eng) Hadden, J. W. (Dept. Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021). *Clin Bull* 8(3): 123-127; 1978.

Research efforts are outlined that were undertaken to determine what undiscovered carcinogenic materials present themselves to the human population, whether very small amounts of known, potent carcinogens in the environment

constitute a risk, which individuals are most susceptible to carcinogens, and what factors may influence this susceptibility. (no refs)

- 79-1829 The Workplace as a Cause of Cancer--Part II.** (Eng) Schottenfeld, D. (Epidemiology and Preventive Medicine Service, Dept. Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Haas, J. F. *Clin Bull* 8(3): 107-119; 1978.

The relevance of animal and in vitro studies for predicting human risks is reviewed. The results of animal and of clinical and epidemiologic studies of industrial agents associated with cancer are tabulated. The agents include federally regulated carcinogens and agents for which epidemiologic and/or animal studies suggest carcinogenic potential. Since it is difficult to determine the 'safe' level of human exposure to any suspect carcinogen with any degree of confidence, the concepts of 'acceptable risk' and 'risk-benefit analysis' are emerging in counterpoint to the issue of a 'risk-free' workplace. (110 refs)

- 79-1830 The "Beer Cancer".** (Ger) Oeser, H. (Kurfurstendamm 37, D-1000 Berlin 15, W. Germany). *Munch Med Wochenschr* 121(8): 256-257; 1979.

A recent newspaper report that beer is carcinogenic is criticized. The beer output in Germany has increased > 300% during 1950-1962. During 1962-1976, the period when an increased cancer mortality could be expected (allowing a latency of 15-20 yr), colon carcinoma has increased 30% and stomach carcinoma has decreased 30%. The total cancer mortality rate for men has increased slightly; if lung cancer is excluded, the rate has declined. (no refs)

- 79-1831 The Biological Effects of Ionizing Radiation.** (Eng) Barnett, M. H. (Div. Training and Medical Applications, Bureau Radiological Health, Food and Drug Admin., Dept. Health, Education, Welfare, Rockville, MD). *Conn Med* 43(2): 75-80; 1979.

The biological effects of ionizing radiation are described. The sequential pattern of these effects, short- and long-term effects, life-span shortening, and carcinogenic, embryological, and genetic aspects are discussed. There is evidence that some effects of radiation constitute nonthreshold phenomena. The occurrence of cancer in radium dial painters, radiologists and dentists, uranium miners, atomic bomb survivors, children irradiated in utero, and patients irradiated for ankylosing spondylitis, thymus enlargement, tinea capitis, and TB (pneumothorax induction) is summarized briefly. (9 refs)

79-1832 Radiation Effects on Pre-natal Development and Their Radiological Significance. (Eng)

Mole, R. H. (Medical Res. Council, Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD, England). *Br J Radiol* 52(614): 89-101; 1979.

The effects of irradiation from medical diagnostic procedures received during the first 4 mo of pregnancy are reviewed. The types of risk considered are death of the developing embryo, birth of a malformed child, and childhood cancer. The overall risk of serious radiation-induced harm following exposure of the embryo or fetus to diagnostic x-rays in the first trimester is most probably in the range 0-1 cases/1,000 women receiving 1 rad tissue dose. The 0-1 cases would mostly be childhood cancer. The natural expectation for the birth of a markedly handicapped child at the end of a normal pregnancy is 1/30. The risk from medical diagnostic procedures would seem to be at least 30 times smaller than this. A recent survey of clinical and experimental information on the developmental effects of irradiation in utero by the United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) is critically reviewed in an appendix. (29 refs)

79-1833 On the Mechanism of Film Neoplastogenesis.

(Eng) Libenson, L. (Western Pennsylvania Hosp., 4800 Friendship Ave., Pittsburgh, PA, 15224); Jena, M. *Med Hypotheses* 5(1): 67-82; 1979.

It is hypothesized that protracted low pH values produced in the cell environment might be both the cause and effect of the neoplastic transformation induced by implanted chemically inert films. The following sequence of changes is suggested. Hindrance of interstitial fluid circulation by the implanted film will induce anoxia and, hence, increased lactic acid production by the cells in the vicinity of the film. The protracted low pH produced by the lactic acid will increase the permeability of the capillaries and elicit high concentrations of plasma protein in the fluid near the film. The low pH will also tend to stimulate the pinocytotic uptake of protein-containing interstitial fluid by the cells. Continuous uptake and catheptic hydrolysis of plasma protein at the lower intrapinosomal pH and further hydrolysis of the formed polypeptides at neutrality or slightly alkaline pH will produce an overabundance of complementary amino acids that will be used to synthesize specific cell proteins and other constituents. The overabundance of nutrients will accelerate synthetic processes and promote cell growth and multiplication. Adaptation of normal cells to survive and multiply at low pH would take place concomitantly with their transformation into neoplastic cells. Deletion of enzymes sensitive to low pH would account for the tendency of the neoplastic cells to converge to a uniform enzymatic pattern regardless of the tissue of origin. (44 refs)

79-1834 Photoimmunology. (Eng) Morison, W. L. (Dept.

Dermatology, Massachusetts General Hosp., Boston, MA, 02114); Parrish, J. A.; Epstein, J. H. *Arch Dermatol* 115(3): 350-355; 1979.

Several aspects of photoimmunology, the study of the effects of nonionizing radiation on normal and abnormal immune function, are reviewed. In animals, the immune system appears to be centrally involved in experimental photocarcinogenesis, and some studies suggest that altered immune function may be a factor in the initiation and growth of UV light-induced neoplasms in humans. (96 refs)

79-1835 Genetics of Resistance of Animals to Viruses: I. Introduction and Studies in Mice. (Eng)

Bang, F. B. (Dept. Pathobiology, The Johns Hopkins Univ., Baltimore, MD). *Adv Virus Res* 23: 269-348; 1978.

Inherited resistance to animal viruses is reviewed. Hypotheses concerning host-virus interactions in plants, *Drosophila*, and other insects are presented, along with a description of the origin and development of inbred mice (mouse genetics). The genetic resistance of mice to arboviruses, mouse hepatitis virus, influenza and miscellaneous acute viral infections, scrapie, mouse leukemia virus, mouse mammary tumor virus, and other viruses causing chronic infections (lactic dehydrogenase virus, cytomegalovirus, polyoma virus, and viruses causing lymphocytic choriomeningitis and slow disease of the CNS) is discussed. For each virus or group of viruses, the following points are covered: measurement of the genetic compatibility of host and virus interaction; whether the inherited resistance follows the predictions of Mendelian ratios; the number of genes involved and the degree to which they are linked; cytoplasmic factors in the host that may modify the virus infection; the ontogeny of resistance in an individual animal; the cellular or tissue type involved in resistance; the ability of drugs or environment to modify genetic resistance; the possible existence of viral variants that overcome cellular genetic resistance; and whether a compatible pair of virus and host cells yield a one-hit curve of lesions. 79-1836 Generation of Diversity among Murine C-Type Viruses via Envelope Gene Recombination.

(Eng) Elder, J. H. (Dept. Cellular and Developmental Immunology, Scripps Clinic and Res. Foundation, La Jolla, CA, 92037); Gautsch, J. W.; Jensen, F. C.; Lerner, R. A. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 553-560; 1978.

Structural analyses of the surface glycoprotein gp70 of the murine C-type viruses that suggest that gp70 plays a central role in the generation of murine C-type virus diversity are reviewed. Tryptic fingerprint analysis of gp70 and the internal proteins p30 and p15 from representatives of the three

main endogenous virus groups (Akv-2 ecotropic virus, 1504A wild mouse amphotropic virus, and NZB xenotropic virus) indicated that p30 and p15 have only subtle group specificity. However, an extreme divergence was observed in the structure of the gp70's from these viruses. Structural analysis of the mink cell-focusing (MCF) virus isolates of AKR mice indicated that recombination between endogenous ecotropic and xenotropic viruses can occur within the envelope gene encoding gp70. This implies that the noncoordinate divergence of gp70 observed in the endogenous C-type viruses was the result of recombination within the envelope gene. In the high leukemia AKR mouse strain, lymphomas begin to develop at 6 mo of age. AKR ecotropic virus is produced throughout life and does not appear to be the direct causative agent in AKR leukemia. Xenotropic virus expression begins in the thymus at 4-6 mo of age, but xenotropic virus alone appears to have no oncogenic potential. MCF virus, however, is produced in the preleukemic and leukemic thymus and is not present in young AKR mice. Tryptic-peptide analysis showed specific homology with xenotropic virus in the gp70 of MCF-247, whereas chymotrypsin cleavage revealed peptides specific for AKR ecotropic virus gp70. The MCF viruses result, therefore, from an intragenic recombination between endogenous ecotropic and xenotropic viruses and may be the true causative agents of AKR lymphoma. (19 refs)

79-1837 Cellular Differentiation and Malignant Transformation. (Fre) Foa, C. (Unite 119, INSERM, boulevard Lei-Roure, F13009 Marseille, France); Nicoli, J.; Meyer, G. *Bull Cancer (Paris)* 66(1): 29-36; 1979.

Studies of cell differentiation and malignant transformation are reviewed with special regard to the development of melanomas and transformation by papovaviruses. Malignant transformation can represent a phenomenon independent of differentiation or it can represent a particular form of differentiation. Transformation by an oncogenic virus is linked with the coding of proteins by the virus genome; these proteins are differentiation inducers. Ultrastructural, cytoenzymatic, and cytogenetic studies of human malignant melanomas have demonstrated that accumulation of melanin and malignancy are often simultaneous, but that there are also melanocytes in which these two phenomena are dissociated; ie, there are highly malignant pigmented cell lines, malignant achromic cell lines, and malignant pigmented cell lines developing secondarily from a nonmalignant, apparently achromic stage. The highly malignant pigmented cells are believed to be melanocytes that have preserved the features of differentiation but have lost their regulation mechanism, whereas the achromic cells present in certain mixed tumors maintain their regulation mechanism and are capable of repressing melanin synthesis. 79-1838 Reptilia-related Viruses. (Eng) Lunger, P. D. (Univ. Delaware, Newark, DE); Clark, H. F.

Adv Virus Res 23: 159-204; 1978.

In-depth studies of reptilian virology are reviewed. The topics covered include DNA and RNA-containing viruses, intramitochondrial viruses, infection of reptilian cell cultures with nonreptilian viruses, interferon production by tortoise cells, and virus-induced reptilian cell transformation. (124 refs)

79-1839 Differentiation and Leukemic Transformation of Thymus-derived Lymphocytes. (Eng) Waksal, S. D. (Cancer Res. Center, Tufts Univ. Sch. Medicine, Boston, MA, 02111). *Cold Spring Harbor Conf Cell Prolif* Vol. 5(Book B), 994 pp.; 641-655; 1978.

Studies of the differentiation and leukemic transformation of thymus-derived lymphocytes are reviewed. A technique has been developed for the culture of thymus epithelium (TE) in monolayers devoid of any lymphocytic elements. Culture of spleen cells from congenitally athymic (nu/nu) mice with congenic TE monolayers resulted in the acquisition of Thy-1, a differentiation antigen associated with mature T lymphocytes, and the induction of helper T-lymphocyte activity. Studies of the responsiveness of prothymocytes and thymocytes to thymic hormone and TE using three types of cell populations as target cells showed that the target cells most reactive to the TE monolayers were least reactive to the hormone. The cells, therefore, lose reactivity to TE monolayers as they acquire reactivity to the hormone. TE derived from aged AKR mice directly initiated leukemic transformation of young AKR thymocytes in vitro, whereas control monolayers from young nonleukemic AKR mice had no such effect. Studies using thymectomized animals indicated that the donor thymocytes could manifest leukemia even in the absence of further differentiation in vivo. The TE cells from aged, but not young, nonleukemic AKR mice contained mink cell focusing virus, one of a new class of recombinant polytropic C-type RNA viruses (ie, both ecotropic and xenotropic host range). It is suggested that this new class of viruses is associated with leukemogenesis. (32 refs)

79-1840 Recent Advances in Polyoma Virus Research. (Eng) Consigli, R. A. (Div. Biology, Kansas State Univ., Manhattan, KS); Center, M. S. *CRC Crit Rev Microbiol* 6(3): 263-299; 1978.

Recent advances made in polyoma virus research, particularly those concerning polyoma infection of a permissive host, are reviewed. The virus genome has been dissected and has been shown to be almost completely saturated with genetic and biological markers. Information concerning the function of each gene product, together with the possible sequence of the viral DNA, will make polyoma and the closely related simian virus 40 the most completely understood of all animal viruses. The early region of the polyoma genome will proba-

bly be known in detail within the next few years. Recent studies have indicated that antiserum to large tumor (T) antigen reacts with a 100,000-dalton (100K) protein and also with a prominent 21K protein, which has been designated small t antigen. This protein may have common sequences with the 100K T-antigen polypeptide. The absence of this protein in cells infected by a mutant with a host range and transformation defect (NG18) suggests that it may be involved in the maintenance of transformation. The mechanism by which the 21K t antigen is made is unknown, but it has been proposed that early messenger RNA is modified such that it is translated to form more than one protein. Early messenger RNA may contain one or more regions that are looped out from the polynucleotide chain; the 100K T antigen may be made from sequences excluding the loop, but the 21K protein may be made from some sequences common to T antigen but also from those containing the loop. VP₃, a viral capsid protein, might play some role in maintaining certain phenotypic properties of the transformed cell. Other studies strongly suggest that the viral capsid protein VP₁ is initiated independently of VP₃. Polyoma virus has been useful and possibly has unlimited potential as a tool or biological probe for understanding host transcriptional and replicative processes. (229 refs)

- 79-1841 **Bovine Leukemia Virus.** (Jpn) Onuma, M. (Dept. Veterinary Medicine, Hokkaido Univ., Sapporo, Hokkaido, Japan 060). *Virus* 28(2): 53-60; 1978.

The morphology and biochemical structure of bovine leukemia virus (BLV), the surface antigens of the bovine lymphosarcoma cells, the method of BLV infectious transfer, and the relationship between sporadic bovine leukemia and BLV are reviewed. (97 refs)

- 79-1842 **Unit of Biological Carcinogenesis.** (Eng) Geser, A. (International Agency Res. Cancer, Lyon, France). *IARC Annual Report* 66-76; 1978.

The 1978 activities of the Unit of Biological Carcinogenesis of the International Agency for Research on Cancer are reported. Etiological studies of Burkitt's lymphoma (BL) and nasopharyngeal carcinoma (NPC) continued to be the main occupation of the Unit. The testing of 14 sera from Ugandan BL patients prior to tumor onset showed that anti-Epstein-Barr virus (EBV)/viral capsid antigen (VCA) activities were significantly increased in BL patients years before tumor appearance. In some cases, however, the EBV/VCA titers were not raised before BL, and the presence of the EBV genome could not be demonstrated. To establish whether a form of BL exists in Africa that is not EBV-associated and to support the serological findings, it was decided that BL detection in the child cohort bled in Uganda between 1972 and 1974 should be continued. The geographical association between the high incidence of malaria and BL is being investi-

gated in Uganda and Tanzania. The fact that BL patients in Uganda did not reveal a higher malaria burden prior to tumor development than controls does not favor the hypothesis that malaria causes BL. However, malaria parasitemia varies drastically daily in children in hyperendemic areas, and a single examination cannot be expected to give a significant difference between BL candidates and controls, even though such a difference may have existed. In Tanzania, sera will be collected from children in one region who are undergoing malaria prophylaxis and from children in another region where chloroquine is not being distributed. In Singapore approx 5,000 Chinese men will be bled and followed for 5 yr to see whether the EBV antibody profile in persons who subsequently develop NPC differs from that of people who do not. Seroepidemiologic and immunogenetic studies of Tunisians are also being conducted. (7 refs)

- 79-1843 **Hepatocellular Carcinoma and Hepatitis B Virus Markers in Europe and U.S.A. (2 Letters to Editor).** (Eng) Omata, M. (Univ. Southern California Liver Unit, John Wesley Hosp., Los Angeles, CA, 90007); Ashcava, M.; Peters, R. L.; Johnson, P. J. *Lancet* 1(8113): 433-434; 1979.

Comments on a paper suggesting a close relation between hepatitis B virus (HBV) infection and hepatocellular carcinoma (HCC) in Greek patients are presented. Although some aspects of the paper are questioned, one group of researchers found a close association between HBV infection and HCC in the US. Another researcher states that to demonstrate a causal relationship between HCC and HBV infection, it is necessary to show that proved noncirrhotic patients have a significantly higher incidence of HBV infection than matched controls or to show that patients dying with cirrhosis complicated by HCC have a higher incidence of HBV infection than those dying with cirrhosis alone. (12 refs)

- 79-1844 **On the Relationship Between Viral Hepatitis and Hepatocarcinoma.** (Eng) Pollice, L. (Inst. Pathological Anatomy, Univ. Bari, Bari, Italy). *Med Hypotheses* 5(2): 253-255; 1979.

Evidence suggesting a possible relationship between hepatitis B virus (HBV) infection and hepatocellular carcinoma (HCC) is reviewed. This evidence includes the observation of hepatitis B surface antigen (HBsAg) in the sera of noncirrhotic patients with HCC, the high incidence of HBsAg positivity among mothers of children with hepatoma, and the fact that hepatic oval cells are a good culture medium for HBV. These cells are also directly involved in α -fetoprotein production, which is markedly elevated in 80% of HCC patients. (21 refs)

- 79-1845 Immunological and Virological Aspects of Cervical Carcinoma.** (Eng) Hillemanns, H. G. (Universitäts-Frauenklinik, Hugstetterstrasse 55, D-7800 Freiburg im Breisgau, W. Germany); Sellin, D.; Petersen, E. E. In: *Cervical Pathology and Colposcopy. Selected Papers from the Second World Congress of Cervical Pathology and Colposcopy held in Graz, Austria, 15-18 October 1975.* Burghardt, E.; Holzer, E.; Jordan, J. A., eds. (Stuttgart: Georg Thieme Publishers): 146 pp.; 97-102; 1978.

Immunological and virological studies concerning cervical carcinoma are reviewed, with particular reference to the relationship between this neoplasm and herpes simplex virus type 2 infection. (17 refs)

- 79-1846 6. Interdisciplinary Programme and International Liaison Unit.** (Eng) Linsell, C. A. (International Agency Res. Cancer, Lyon, France). *IARC Annual Report* 121-131; 1978.

The 1978 activities of the Interdisciplinary Programme and International Liaison Unit of the International Agency for Research on Cancer are reported. Priority areas for cancer research in developing countries are identified, and progress in studies of cancer immunology, prenatal events and childhood cancer, liver cancer, and esophageal cancer is summarized. (8 refs)

- 79-1847 Immunodeficiency Diseases and Malignancy.** (Eng) Spector, B. D. (Dept. Lab. Medicine and Pathology, Univ. Minnesota, Minneapolis, MN, 55455); Good, R. A.; Kersey, J. H. In: *Gastrointestinal Tract Cancer.* Lipkin, M.; Good, R. A., eds. (New York, London: Plenum Medical Book Co.): Sloan Kettering Inst. Cancer Series 602 pp.; pp. 51-70; 1978.

This review of immunodeficiency (ID) diseases and malignancy is based on 205 reported cases of cancer occurring in patients with primary ID diseases. The ID diseases occurring in these patients included X-linked agammaglobulinemia (12 cases), IgA deficiency (13), IgM deficiency (7), variable ID (58), severe combined ID (11), ataxia-telangiectasia (70), and Wiskott-Aldrich syndrome (34). Each primary ID disease was associated with a significant number of lymphoreticular tumors, which accounted for 57% of all cancers and for the majority of cell types in 5/7 primary ID's. The distribution of cancers by age and primary site indirectly supports the conclusion that immunodeficient patients are at greatly-increased risk for developing cancer. The high male-female ratio (2:1) can be attributed to the X-linked disorders of childhood. Sex became a less significant variable beyond childhood. There was a surprisingly large number of gastrointestinal malignancies (26), particularly stomach cancers (18). Primary ID diseases likely provide a dramatic example of the influence of genetic factors on malignancy, since the lym-

phoid apparatus in individuals with these diseases is both the site of genetic aberration and the principal site of cancer development. Hypotheses of the mechanisms of lymphoid system oncogenesis fall into at least two categories: (1) the immune system in primary ID's is subject to the formation of too many malignant cells; and (2) the immune system in these diseases has a decreased ability to recognize and destroy malignant cells. Pathogenic mechanisms that may be responsible for the increased transformation of lymphoid cells include intrinsic defects in lymphoid cells, chronic antigenic stimulation, the activation of endogenous viruses or infection with exogenous oncogenic viruses, and the lack of regulatory feedback mechanisms, which results in enhanced lymphoid proliferation. (74 refs)

- 79-1848 The Structure of H-2 Antigens and Their Role in Tumor Cell Recognition.** (Eng) Cunningham, B. A. (Dept. Developmental and Molecular Biology, Rockefeller Univ., New York, NY, 10021); Milner, R. J.; Schrader, J. W.; Reske, K.; Henning, R.; Ziffer, J. A.; Edelman, G. M. *30th Ann Symp Cancer Res* 163-176; 1978.

The structure of the major histocompatibility (H-2) antigens of the mouse and their role in the lysis of tumor cells and virally infected cells by cytotoxic T lymphocytes are reviewed. The genes for the H-2 antigens are located in two closely linked loci (H-2K and H-2D) on the 17th chromosome and are characterized by extensive polymorphism. Between these loci are two other regions: the I region contains immune response genes and the S region contains genes specifying a serum protein and its sex-linked variant. These data suggest that the H-2 complex contains a variety of genes that arose by duplication. In addition, two regions, T1a and the t-complex, which are outside the H-2 complex but are on the 17th chromosome, may have similar properties with regard to the immune system. The sequences and amino acid compositions of the β -microglobulin of several species indicate that it is a highly conserved protein. No variant has been detected within a species by serological techniques or by amino acid sequence analysis. The most striking feature of the human protein is its similarity to the constant homology regions of all immunoglobulins, indicating that they probably share a common evolutionary origin. The amino acid sequences and products of the H-2K and H-2D alleles are also similar, suggesting that these two regions arose by duplication of an ancestral gene. The similarity between H-2 and the human major histocompatibility (HLA) antigen sequences also supports the conclusion that these two systems serve the same function. H-2 antigens are intimately involved in the lysis of virally infected and tumor cells by cytotoxic T cells. Thus, it is likely that the cytotoxic T cell has a single receptor and the H-2 molecule is part of or directly affects a single component on the target cell, or the cytotoxic cell has two separate receptors that recognize the target antigen and the H-2 molecule independently. Present evidence favors the first model. (44 refs)

- 79-1849 Transplantation in Nature.** (Eng) Beer, A. E. (Univ. Texas Health Science Center, 5323 Harry Hines Blvd., Dallas, TX, 75235); Billingham, R. E. *Perspect Biol Med* 22(2, part 2): 155-169; 1979.

An account of certain exceptional situations in nature in which successful allotransplantation occurs is presented. Topics discussed include parabiotic unions in deep-sea angler fish, synchorial twinning in cattle, a venereally transmissible tumor in dogs, maternal-to-fetal transmission of malignant melanoma in humans, mammalian reproduction and transplantation, deportation of trophoblasts, choriocarcinoma, maternally induced runt disease, and suckling as a possible form of transplantation. (22 refs)

- 79-1850 Polypeptides Regulating Lymphocyte Differentiation.** (Eng) Goldstein, G. (Ortho Pharmaceutical Corp., Raritan, NJ, 08869). *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 455-465; 1978.

The isolation, chemical structure, site of production, and actions of several polypeptides associated with the regulation of lymphocyte differentiation are reported. Thymopoietin, which is synthesized and secreted by epithelial cells of the thymus, induced the differentiation of prothymocytes to thymocytes in vitro and in vivo. Thymopoietin induction of prothymocyte-to-thymocyte differentiation is mediated by a cAMP second signal. Thymopoietin also affects a number of tissues, including T cells, B cells, macrophages, granulocytes, and the neuromuscular junction, suggesting that it also functions as a hormone. These actions appeared to be mediated by cyclic guanosine monophosphate as a second signal. Ubiquitin has been found in all mammalian tissues and does not appear to be implicated as a physiological regulatory molecule for lymphocyte differentiation; it may function as a structural or controlling element related to DNA. Another peptide, termed the Bach nonapeptide, is a circulating peptide with potent actions on lymphocyte differentiation, but its source of production and circulating levels are not yet known. Bursopoietin is a short peptide purified from chicken bursa of Fabricius. Preliminary studies have demonstrated that it has a B-cell-differentiating activity. It is concluded that thymopoietin, bursopoietin, and perhaps the Bach nonapeptide induce the differentiation of committed early precursor cells and possibly regulate the activities of differentiated cells in a hormonal rather than in an inductive sense. (39 refs)

- 79-1851 Regulatory Interactions in Normal and Leukemic Myelopoiesis.** (Eng) Moore, M. A. (Sloan-Kettering Inst. Cancer Res., New York, NY, 10021); Kurland, J.; Broxmeyer, H. E. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 393-404; 1978.

Functional and regulatory characterization of leukemic cell

lines derived from in vivo tumors or from tumors that developed spontaneously in in vitro continuous bone-marrow culture is discussed. Constitutive production of colony-stimulating factor (CSF) characterized cultures of murine peritoneal macrophages, and it could be increased by the addition of lipopolysaccharide (LPS). Macrophages generated from bone marrow-derived granulocyte-macrophage committed stem cells (colony-forming unit--culture, CFU-C) and 3/4 neoplastic monocyte or macrophage cell lines were not constitutive CSF producers but were capable of production following LPS stimulation. In vitro activation of normal peritoneal macrophages and in vitro-generated macrophages with LPS produced a 10-fold and 5-fold increase in prostaglandin E (PGE) production, respectively. A similar linkage between induction of CSF and subsequent synthesis of PGE was observed in the monocyte-macrophage cell lines. Production of PGE by normal or neoplastic B or T lymphocytes was not observed. Spontaneous transformations observed in allogeneic continuous bone-marrow cultures were characterized by an increased rate of cell production, development of agar cloning capacity in the absence of CSF, and failure of the cells to mature. These events were paralleled by marked aneuploidy, capacity of the cell to grow continuously in the absence of an adherent marrow cell population, and tumorigenic potential in nude mice or normal mice syngeneic with the second marrow cell population. Transformation was also observed in syngeneic cultures of CBA bone marrow plus fetal liver cells. These models of spontaneous in vitro leukemogenesis may reflect events associated with natural leukemogenesis more accurately than transformation systems involving infection with murine leukemia viruses. (22 refs)

- 79-1852 Plasmacytomagenesis and the Differentiation of Immunoglobulin-producing Cells.** (Eng) Potter, M. (Lab. Cell Biology, NCI, Bethesda, MD, 20014); Cancro, M. *30th Ann Symp Cancer Res* 145-161; 1978.

The relationship between plasmacytomagenesis and the differentiation of immunoglobulin (Ig)-producing cells is reviewed. Evidence is presented that suggests that the progenitors of plasmacytomas in the BALB/c mouse system are derived from a relatively specific subpopulation of B lymphocytes that are generally in a comparatively late stage of differentiation. IgA-producing cells are implicated as the progenitor subpopulation. These cells probably originate as rarely occurring members of the B-lymphocyte subpopulation that lack or escape normal regulatory constraints with respect to their proliferative capacity. They then attain clonal sizes that emerge as detectable plasmacytomas through interactions with unusual, perhaps selective, microenvironmental influences that enhance their expansion and survival. The inbred-strain susceptibility implicates germ-line genes as playing a role in BALB/c plasmacytomagenesis. The effect of the gene(s) may only be to increase the probability of neoplastic change, however, and may not be the sole determinant. Other mutational events (somatic mutations, C-type RNA virus production) may complement germ-line genes

that govern susceptibility. A powerful influence in plasmacytomagenesis is the promoting effect of the oil granuloma, which may also act as a selecting factor that favors the growth of potential or preplasmacytoma cells. (68 refs)

- 79-1853 Ocular Tumor Immunology.** (Eng) Char, D. H. (Dept. Ophthalmology, Francis I. Proctor Foundation, Univ. California, San Francisco, CA). *Current Ophthalmology*: 74-100; 1978.

Several clinical and laboratory observations are consistent with the hypothesis that immunologic factors may be important in ocular malignancy. The possible role of the immune system in the host-tumor interaction is reviewed, and possible diagnostic and prognostic immunologic tests are presented. (93 refs)

- 79-1854 Bacterial Metabolism and Colon Cancer.** (Eng) Hill, M. J. (Bacterial Metabolism Res. Lab., Central Public Health Lab., Colindale Ave., London NW9 5HT, England). *Nutr and Cancer* 1(2): 46-50; 1979.

There are several possible substrates for carcinogen production by intestinal bacterial flora from dietary meat. Fecal tryptophan concentrations are much higher in large bowel cancer (LBC) patients than in controls, and in a study of six populations there was a relation between fecal tryptophan concentration and the incidence of LBC. The concentration increased with increased dietary protein. Methionine can be converted to ethionine, which is carcinogenic in rats, in the presence of sulfate ions by several bacteria. Lysine, arginine, ornithine, and lecithin are metabolized by the gut flora to cyclic secondary amines that are N-nitrosatable in the presence of nitrate. However, if the production of N-nitrosamine by bacterial action in the colon were important in large bowel carcinogenesis, the disease should be associated geographically with high levels of dietary nitrate. In fact, this is not so. Evidence linking cholesterol and/or its metabolites with colon cancer is contradictory. Fecal bile acid concentration is related to the amount of dietary fat. There is much evidence incriminating fecal bile acid metabolites in LBC. The fecal concentration of deoxycholic acid correlated well with the incidence of LBC in nine populations, but it was no better than total fecal bile acids as a discriminant in a case-control study. The results of this study are compatible with the postulate that the cocarcinogen causing LBC is an unsaturated bile acid, perhaps a 4,6-dien-3-one, produced by certain Clostridia from colonic bile acids. (35 refs)

- 79-1855 Recognitive Immunity in Colon Cancer.** (Eng) Berlinger, N. T. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021). In: *Gastrointestinal Tract Cancer*. Lipkin, M.; Good, R. A., eds. (New York,

London: Plenum Medical Book Co.): Sloan Kettering Inst. Cancer Series 602 pp.; pp. 71-92; 1978.

Evidence supporting the antigenicity of colon carcinomas, tests of recognitive immunity in the colon carcinoma patient, and escape mechanisms by which tumors continue to grow in patients who have demonstrated immune reactivity to tumor cells in vitro are reviewed. The antigenicity of colon carcinomas has been suggested by the results of serological studies, delayed hypersensitivity skin testing, and in vitro studies; the apparent specificity of colon carcinoma antigens; and evidence that the colon carcinoma antigen behaves like a true immunogenic substance. Diverse tests of recognitive immune function to various stimuli have been developed; if the patient is hyporesponsive in this regard, it may be logical to consider his tumor defense mechanisms to be deficient. Morphological tests of recognitive immune function involve determining the degree of lymphocytic infiltration of tumors and the lymph node histology. Another test of cellular immune function involves measuring the ability to mount a cutaneous delayed hypersensitivity reaction to intradermally injected, commonly encountered antigens. A third test is the mixed leukocyte assay. One reason that tumors continue to grow in patients who have demonstrated immune reactivity to tumor cells is that cells of certain tumors may be only weakly antigenic and may not provide a strong enough stimulus to provoke optimal recognitive and effector responses. Alternatively, the infrequent antitumor immunoreactivity observed in cases of poorly differentiated tumors may be due to the fact that these tumors are more widely spread and are, by some unknown mechanism, leading to immunological paralysis. A role for antibody has also been postulated in the mechanism by which tumors escape immune attack. (110 refs)

- 79-1856 Effects of Anaesthesia and Surgery on Immune Status.** (Eng) Walton, B. (Dept. Anaesthetics, London Hosp., London E1 1BB, England). *Br J Anaesth* 51(1): 37-43; 1979.

Evidence that exposure to anesthesia + surgery (A+S) alters many facets of immunocompetence is reviewed, particularly the possible clinical implications for anesthetic practice. A+S may alter immunocompetence by depressing a variety of both nonspecific resistance mechanisms and specific immune responses. In general, the hormonal aspects of the stress of A+S are more important with regard to immunosuppression after operation and possible development of malignancy than anesthetic regimes per se, the effects of which are short-lived. (103 refs)

- 79-1857 Cancer: The Survival of the Fittest.** (Eng) Markert, C. L. (Dept. Biology, Yale Univ., New Haven, CT, 06520). *30th Ann Symp Cancer Res* 9-22; 1978.

Neoplasias are defined as diseases of cell differentiation stemming from a misprogramming of normal gene function. This misprogramming can have many causes, but all cancer must act by changing the function of regulatory DNA. Ultimately, it is the pattern of gene activity that defines each kind of differentiated cell and each kind of neoplastic cell. With respect to rate of cell division, metastasis, and patterns of metabolism, neoplastic cells resemble some types of normal cells. They out-compete normal cells for ecological space, for the requirements for survival and reproduction. It is likely that several events, at least some of them possibly mutations, must accumulate in a cell before it becomes neoplastic. It is also likely that the frequency of neoplasias is reduced by the presence of such a tight, interdependent cellular organization that almost every aberrant step by any cell would prove fatal to that cell or prevent proliferation. The immune system is probably not very important in combating cancer. Neoplastic agents, including carcinogenic chemicals, physiological stress, and oncogenic viruses, probably all act by altering the regulatory DNA of the host cell genome so as to reprogram gene function in a neoplastic pattern. Inherited teratogenic development may be a nonmalignant expression of the same general kind of misprogrammed gene function stemming from changes in the regulatory DNA at critical stages in embryonic development. - 79-1858 Neoplasms as Caricatures of Tissue Renewal.** (Eng) Pierce, G. B. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO, 80262); Cox, W. F. *30th Ann Symp Cancer Res* 57-66; 1979.

Study of tumor development has led to the concept that tumors are caricatures of the renewal process in normal tissues. Embryoid bodies derived from mouse teratocarcinomas and transplanted sc into mice gave rise to teratocarcinomas containing 12 or 15 somatic tissues characteristic of the tumors. It was concluded that embryonal carcinoma cells are the multipotential stem cells of teratocarcinomas capable of differentiating into functional and benign cells. These cells are also capable of participating in normal development evolving normal animals. Whereas teratocarcinomas are considered caricatures of embryogenesis, squamous cell carcinomas and adenocarcinomas of the breast are considered to be caricatures of tissue genesis. The target in carcinogenesis is probably an undifferentiated cell. The observation that normal and neoplastic stem cells are similar in their degree of differentiation sheds new light on the relationship of benign and malignant tumors. When chemical carcinogens are applied to the skin of an animal, benign tumors appear first, followed much later by the appearance of malignant tumors. This has led to the concept that the state of differentiation of the responding cell could determine the state of differentiation of the neoplastic stem cells derived from it and the order of appearance of tumors would depend on how well the neoplastic stem cell could respond to the environment in which it found itself. The long latent period in carcinogenesis may be due to the

growth-controlling effect of the normal environment on undifferentiated malignant stem cells. (22 refs)

- 79-1859 Quality Assurance for Pathology in Rodent Carcinogenesis Tests.** (Eng) Ward, J. M. (Carcinogenesis Testing Program, NCI, NIH, Del Ray 402, Bethesda, MD, 20014); Goodman, D. G.; Griesemer, R. A.; Hardisty, J. F.; Schueler, R. L.; Squire, R. A.; Strandberg, J. D. *J Environ Pathol & Toxicol* 2(2): 371-378; 1978.

The pathology methods and quality control procedures recommended and utilized by the National Cancer Institute Carcinogenesis Testing Program are reviewed. The necropsy examination involves systematic inspection of external and internal organs and tissues so that tumors and lesions can be detected prior to microscopic examination. Fixation, trimming, dehydration, embedding in paraffin, and sectioning of tissues should be performed by a pathologist or qualified technician, and the histopathologic examination should be performed by a pathologist. One pathologist evaluates all slides from all animals of the same species in each study. A quality assurance unit is recommended for assessing diagnoses and procedures in large-scale programs involving many pathologists from different laboratories. After review by this unit, the original pathologist is notified of important disagreements with his diagnoses and differences of opinion may be reconciled. The use of a computer-based system for recording diagnoses in a large study is desirable. The final report should be a concise and accurate reflection of the findings in both control and treated animals. (13 refs)

- 79-1860 Cytoskeletal Changes in Cell Transformation to Malignancy.** (Eng) Brinkley, B. R. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX, 77030); Miller, C. L.; Fuseler, J. W.; Pepper, D. A.; Wible, L. J. *30th Ann Symp Cancer Res* 419-450; 1978.

The structure, assembly, and distribution of microtubules and microfilament in normal and transformed cells are reviewed. In normal cells, the microtubules are arranged in an elaborate complex throughout the cytoplasm. This cytoplasmic microtubule complex (CMTC) is disassembled at the beginning of mitosis and is replaced by a mitotic apparatus that segregates the chromosomes during mitosis. When mitosis is completed, the CMTC reappears in each daughter cell. Bundles of microfilament actin "stress fibers" also appear in the cytoplasm. They behave similarly to the microtubules during the cell cycle, and both structures seem to be involved in maintaining the cell shape. The major microtubule-organizing center appears to be in the centrosphere region of the cell containing the centrioles and associated organelles. The cytoplasmic microtubules are disassembled by colcemid, chilling to 0-4 C, ionophore A23187 + elevated Ca (4.7 mM), local anesthetics, trypsin, neuraminidase, and, to a lesser extent, cytochalasin B. The CMTC becomes more organized in the

presence of cyclic nucleotides. The cytoplasmic microtubules and microfilaments are reduced in number and more randomly oriented in transformed cells. There is an apparent correlation between the acquisition of anchorage-independent growth in vitro and the diminution of cytoskeletal elements. (72 refs)

- 79-1861 Cell Differentiation and Cancer--A Summary.** (Eng) Paul, J. (Beatson Inst. Cancer Res., Wolfson Lab. Molecular Pathology, Bearsden, Glasgow G61 1BD, Scotland). *30th Ann Symp Cancer Res* 525-532; 1978.

Highlights of papers presented at a symposium on cell differentiation and cancer are summarized. Cancer is essentially an environmental disease, which suggests that the basic lesion may be mutation. With regard to systems that neutralize the effects of mutations, the concepts of immune surveillance and the existence of highly efficient DNA repair mechanisms in multicellular creatures are not supported by the available evidence. It is more likely that the developing organism has a mechanism for selecting against abnormal cells. The fact that normal mice can be derived from teratocarcinoma cells demonstrates that normal tissues can be derived from tumor cells. Furthermore, different kinds of cancers can derive directly from stem cells; the transformed cell of leukemia may actually be a stem cell in one of the late transit populations. Many tumors can revert to more normal tissue by differentiation. common quantitative differences that are characteristic of tumor cells can be exploited in the diagnosis and management of cancer. Finally, there is some doubt that a round of DNA replication is necessary for the process of commitment to differentiation. (8 refs)

- 79-1862 Selectivity and Rejectivity in Cancer Metastasis.** (Eng) Onuigbo, W. I. (Dept. Histopathology, Teaching Hosp., Enugu, Nigeria). *Med Hypotheses* 5(1): 185-191; 1979.

The concepts of selectivity and rejectivity are discussed in relation to cancer metastasis. Selectivity denotes the formation of a secondary tumor in an organ such that its localization pattern is peculiar. The opposite phenomenon is termed rejectivity. In humans, carcinomas appear to spread selectively to the umbilicus, whereas lymphomas seem to reject that site. All carcinomas do not show the same degree of selectivity for the umbilicus. In descending order, most umbilical metastases arise from the stomach, ovary, large bowel, pancreas, gallbladder, uterus, liver, and small bowel. It also appears that lymphomas are likely to show some differences with reference to rejectivity. Although as many as 128 cases of carcinoma of the umbilicus were recorded at the Mayo Clinic over the period 1950-1974, specific mention was not made of the absence of lymphomas in that series. It is suggested that prospective series should encompass both carcinomas and lymphomas. (41 refs)

- 79-1863 Proliferative Homeostasis and Its Age-related Aberrations.** (Eng) Martin, G. M. (Dept. Pathology, Univ. Washington, Seattle, WA, 98195). *Mech Ageing Dev* 9(5/6): 385-391; 1979.

The altered proliferative homeostasis that occurs in aging tissues often leads to multifocal proliferations or hyperplasias. The most important consequence of this age-related hyperplasia is that it could set the stage for tumor promotion--the second stage of the classical two-stage mechanism of chemical carcinogenesis. (45 refs)

- 79-1864 Developmental Genetics of Neural Tumors in Man.** (Eng) Knudson, A. G. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA, 19111); Meadows, A. T. *30th Ann Symp Cancer Res* 83-92; 1978.

The developmental specificities of the genes responsible for familial cases of CNS tumors are reviewed. Oncogenesis in cases of retinoblastoma, 40% of which are heritable in a dominant fashion, has been viewed as a two-step (mutation) process. In the hereditary form, one step is inherited and the other is somatic; in the nonhereditary form, both steps are somatic. Some cases of neuroblastoma and the more mature benign tumor ganglioneuroma are also attributable to a dominant gene that demonstrates considerable specificity. Over 20% of the cases of pheochromocytoma, a benign tumor that is not associated with neuroblastoma or ganglioneuroma, are apparently associated with a highly specific dominant gene. Specific dominant genes also appear to predispose to glioma and medulloblastoma, whereas the dominant gene for neurofibromatosis demonstrates less specificity and predisposes to an array of neural tumors. It is concluded that the normal alleles of neural tumor genes perform crucial functions in the development of the CNS. (31 refs)

- 79-1865 B-Lymphocyte Development and Growth Regulation.** (Eng) Melchers, F. (Basel Inst. Immunology, Basel, Switzerland). *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 485-503; 1978.

Studies of the development and growth regulation of B lymphocytes are reviewed. Studies using fetal mouse liver indicated that precursor B cells can divide in vitro under appropriate culture conditions, that this division is independent of exogenously added mitogen (lipopolysaccharide, LPS), and that these dividing precursors do not secrete immunoglobulin (Ig) to the extent that it could be monitored by a plaque. At the stage of differentiation at which B cells become surface Ig-positive and mitogen-sensitive, they fall into a resting state in which they do not synthesize DNA, do not divide, and appear small in size. One of the earliest changes detected in small B cells after mitogenic stimulation is the induction of IgM secretion, which precedes DNA synthesis within the cell cycle. The ratios of the rates of IgM synthesis over those of

all proteins made in the cell increase with increasing time of stimulation. Clonal analysis of B-cell growth indicates that B cells can balance within the cell cycle between growth and maturation to IgM secretion. An apparent difference demonstrated in reactivity to anti-Ig antibodies and the subsequent mitogenic stimulation of more immature (bone marrow) and mature (adult spleen) B cells may suggest that the proposed complexes of Ig molecules and mitogen receptors exist in different conformations in these two types of B cells. Inhibition of maturation to Ig secretion but not of growth by anti-Ig antibodies of mature splenic B cells stimulated by LPS also suggests that a balance between growth and maturation exists within the cell cycle of growing B cells. (48 refs)

79-1866 Nonrandom Involvement of Chromosomal Segments in Human Hematologic Malignancies.

(Eng) Rowley, J. D. (Dept. Medicine, Univ. Chicago, Chicago, IL, 60637). *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 709-722; 1978.

Studies of chromosome patterns in leukemia are reviewed, and the question of how and why nonrandom changes occur is considered. The first consistent chromosome abnormality identified in a human cancer was the Philadelphia (Ph¹) chromosome in leukemic cells from patients with chronic myelogenous leukemia (CML). The Ph¹ chromosome represents a translocation involving chromosomes 9 and 22. The 9:22 translocation was identified in 529/569 Ph¹ CML patients examined with banding techniques. In 100/135 CML patients in the terminal acute phase, additional chromosomal abnormalities were superimposed on the Ph¹ chromosome. In patients with acute nonlymphocytic leukemia, the most frequently observed chromosomal changes were a gain of number 8 and a loss of number 7. In patients with acute myeloblastic leukemia, a translocation involving numbers 8 and 21 was seen in 10%-15% of all patients with aneuploidy and it was frequently associated with the loss of a sex chromosome. Another consistent abnormality, a 15:17 translocation, was identified in acute promyelocytic leukemia. Studies of patients with hematological disorders who were trisomic for all or part of chromosome 1 have identified a specific region of chromosome 1 that is invariably present in the trisomic state in patients who have an excess of any part of 1. The mechanism for the production of specific, consistent reciprocal translocations is unknown. Preliminary studies of chromosome-gene correlations suggest that nonrandom chromosome aberrations change the level of some enzymes related to nucleic acid metabolism and that they may be an important component in the proliferative advantage of mutant cells in neoplasia. (35 refs)

79-1867 Regulation of Normal Cell Differentiation and Malignancy in Myeloid Leukemia. (Eng) Sachs,

L. (Dept. Genetics, Weizmann Inst. Science, Rehovot, Israel). *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book

A), 528 pp.; 411-423; 1978.

Studies of the regulation of normal cell differentiation and malignancy in myeloid leukemia are reviewed. Normal myeloid precursors can be induced to differentiate to mature macrophages and granulocytes by the protein inducer MGI (macrophage and granulocyte inducer). One type of myeloid leukemic cell in humans (MGI+D+) can be induced to differentiate normally both in vitro and in vivo by MGI. The mature cells induced from MGI+D+ leukemic cells were no longer malignant in vivo and no longer multiplied in vitro. Both normal cells and MGI+D+ leukemic cells were induced by MGI to produce the same mature cells, and the process of differentiation occurred in the same sequence. The MGI+D+ leukemic cells were viable and could grow in the absence of MGI, whereas the normal cells required MGI for cell viability and growth. The change in requirement for MGI for cell viability was associated with a chromosome abnormality, which suggests a genetic origin for this leukemia. Once the change in requirement for MGI occurred, many other markers were induced that could be used for the genetic dissection of the controls for normal differentiation in these cells. Differences in competence for induction of normal differentiation in myeloid leukemic cells by MGI were associated with membrane differences between MGI+D+ and the less competent cells. Karyotype analysis has shown that the genes that control cell competence are located on mouse chromosomes 2 and 12 and that inducibility by MGI is controlled by the balance between these genes. Some of the stages of differentiation could be induced by certain steroids, but MGI is the only compound tested that induced all the changes to mature macrophages and granulocytes. Certain clones of leukemic cells could be induced by lipopolysaccharides to produce their own MGI. (59 refs)

79-1868 Interrelationship of Differentiation and Proliferation Control in Hemopoietic Stem Cells.

(Eng) Lajtha, L. G. (Paterson Labs., Christie Hosp. and Holt Radium Inst., Manchester M20 9BX, England); Lord, B. I.; Dexter, T. M.; Wright, E. G.; Allen, T. D. *30th Ann Symp Cancer Res* 179-193; 1978.

Proliferation control of hemopoietic stem cells operates at two levels: control of the 10-12 amplifying divisions during the transient life of the differentiated and maturing 'transit populations' and control of the steady-state maintenance of the stem cells. Regarding the transit populations, evidence exists for an apparent cell-line-specific feedback proliferation control in granulocytic, erythroid, and lymphocytic cells. Maintenance of stem cells in the noncycling G₀ state appears to be under the 'local' control of the spleen or bone marrow and dependent on local stem cell concentration. This local maintenance can be overridden by direct stimulation of the effective pathways of cell proliferation or by more physiological feedback information following depopulation of, for example, committed descendant cell populations. Stem cell inhibitors and stimulators can be used in combination to

manipulate the cycling of the stem cells, and they might have a role in manipulation of the drug sensitivity and recovery rate of hemopoietic cells during chemotherapy. A long-term bone marrow culture system has been developed in which stem cell maintenance and differentiation can be maintained for several weeks. The same method applied to human bone marrow might be useful for the study of human pluripotent stem cells. (42 refs)

79-1869 Regulation of Proliferation and Maturation at Early and Late Stages of Erythroid Differentiation. (Eng) Iscove, N. N. (Basel Inst. Immunology, CH4058 Basel, Switzerland). *30th Ann Symp Cancer Res* 195-209; 1978.

Regulation of the proliferation and maturation of RBC's from multipotential stem cells (MSC) to proerythroblasts is discussed. The initial event is the transition from MSC to cells that have lost the capacity for granulocyte-macrophage differentiation while retaining the potential for erythroid and megakaryocytic differentiation. These cells remain similar to the parent stem cells in size, density, low proliferative activity in the steady state, and responsiveness to regulatory influences in vivo. The next stage covers a spectrum characterized by the gradual onset of sensitivity to high concentrations of erythropoietin. The cells increase their proliferative capacity and become increasingly dependent on erythropoietin for maintenance of this capacity. Transition through this stage is influenced by an environmental cue related to the *s/l* gene product. Erythroid colony-forming units represent the final stage in the series. Their formation can take up to 8-12 days. They are larger and denser than the earliest cells, are highly erythropoietin-sensitive, and exhibit max proliferation. In the absence of erythropoietin, they lose their ability to respond to it when re-exposed. This stage precedes the onset of Hb synthesis by 24-30 hr. (31 refs)

79-1870 Bone Morphodifferentiation and Tumorigenesis. (Eng) Urist, M. R. (Bone Res. Lab., Univ. California, 1000 Veteran Ave., Los Angeles, CA, 90024). *Perspect Biol Med* 22(2, part 2): S89-S113; 1979.

Current knowledge of bone morphodifferentiation and tumorigenesis is reviewed. Bone morphogenesis is the process of controlled growth and development of bone tissue with the normal complement of bone marrow, whereas bone tumorigenesis is the process of uncontrolled bone cell growth without the normal complement of bone marrow. Methods have been devised for identifying and measuring the products but not the initiating agents of differentiation. The expectations are that quantitation of cell products will lend some clues as to the initiating agents or causal conditions. Experiments on nontumorous and tumorous bone suggest that extracellular matrix products include a bone morphogenetic protein, but only normal and not transformed cells are able to respond

to it. The development of the bone tissue cell types--mesenchymal cells, preosteoblasts, osteoblasts, and osteocytes--stops at the osteoblast stage. In Dunn osteosarcomas, transformed osteoblasts may replicate at a rate that is as much as 10 times that of preosteoblasts of even a rapidly developing fetus, but they fail to develop into mature osteocytes. It is not known why this is so. Normally, osteoblasts do not undergo mitotic division. Abnormally, the process of uncontrolled replication of osteoblasts establishes an antithetical relationship of bone morphogenesis and tumorigenesis. It appears that a combination of genetic, cytological, and local environmental agents is involved in bone tumorigenesis. (37 refs)

79-1871 The Precursors of Cutaneous Squamous Cell Carcinoma. (Eng) Brownstein, M. H. (Lab. Dermatopathology, Great Neck, NY, 11022); Rabinowitz, A. D. *Int J Dermatol* 18(1): 1-16; 1979.

Data on the cause, incidence, and histology of several precursors of squamous cell (epidermoid) carcinoma (scc) are reviewed. Cellular atypia (dysplasia) is present in premalignant lesions such as solar keratosis and Bowen's disease, and it is an indication that invasive scc may eventuate. Premalignancy is recognized microscopically as a disturbance of normal epidermal maturation, including loss of polarity, variation in shape and size of cells, nuclear hyperchromatism, prominent nucleoli, and abnormal mitotic figures. Although precursors of scc may have a wide variety of causes, histologically, they display only two basic patterns: bowenoid (in Bowen's disease; erythroplasia of Queyrat; intraepidermal epithelioma; bowenoid solar, arsenical, and radiation keratosis; leukoplakia; and base of cutaneous horn) and solar keratosis-like (in solar, arsenical and radiation keratosis; leukoplakia; and cutaneous horn). Carcinoma in situ, or intraepidermal carcinoma, is an advanced premalignant lesion with marked cellular pleomorphism in which the entire thickness of the epidermis may show the cytologic features of malignancy. Even though the morphologic criteria of malignancy may be satisfied, the term premalignant is used to indicate that, in a biologic sense, invasive malignancy has not yet occurred. Invasive scc sometimes develops at the site of a previous benign condition. In dermatoses such as lichen sclerosus et atrophicus of the vulva and epidermolysis bullosa, cellular atypia is not seen in the early stages; in some patients, however, cellular atypia and invasive malignancy develop later. (79 refs)

79-1872 Glomus Tumor of the Middle Ear: Origin, Symptomatology, and Treatment. (Eng) Bratt, G. W. (Div. Hearing and Speech Sciences, Vanderbilt Univ. Sch. Medicine, 1114 19th Ave. South, Nashville, TN, 37212); Bess, F. H.; Miller, G. W.; Glasscock, M. E. *J Speech Hear Disord* 44(1): 121-134; 1979.

The origin, symptomatology, and treatment of glomus tumor (GT) are reviewed. GT is histologically similar to the glomus jugulare body from which it arises; it is a blood vessel tumor with interspersed epithelioid cells. Unlike the glomus jugulare body, the tumor is much more common in women than in men. The incidence of GT, like that of the glomus body, is most prevalent in middle age and is rare in preadolescence. A review of 40 cases of GT (20 glomus tympanicum and 20 glomus jugulare) revealed that 38 of the tumors occurred in women. The mean age of the patients was 50.6 yr. The most prevalent clinical symptoms in both jugulare and tympanicum tumors were tinnitus and hearing loss. Although the prevalence of symptoms between the two types of glomus tumors was generally similar, two significant dissimilarities were noted. First, the incidence of early dizziness was higher in the tympanicum group than in the jugulare group. Secondly, although the incidence of hoarseness in the total population was low, hoarseness was associated only with the jugulare tumor. (42 refs)

79-1873 Induction of Pancreatic Tumors in Syrian Golden Hamsters (Meeting Abstract). (Eng) Levitt, M. H. (Tumor Pathology Branch, NCI, Bethesda, MD, 20014). *Lab Invest* 40(2): 268-269; 1979. (4 refs)

79-1874 The Pathogenesis and Frequency of Primary Carcinoma after Stomach Surgery. (Ger) Peitsch, W. (Klinik und Poliklinik für Allgemeinchirurgie, Universität Göttingen, Robert-Koch-Strasse 40, D-3400 Göttingen, W. Germany); Becker, H. D. *Chirurg* 50(1): 33-38; 1979.

Several clinical and experimental studies of the incidence of stomach carcinoma (SCa) after surgical (Billroth II) or conservative (nonsurgical) treatment for stomach ulcers are reviewed. Studies in which a large number (≥ 500) patients and an equal number of controls with the same underlying disease were periodically examined during the period 5-30 yr after surgery and in which histological study established the benign nature of the underlying disease revealed that the SCa incidence associated with Billroth II stomach resection ranges from 7% to 16%. Patients who had a Billroth II resection for duodenal ulcers had an SCa incidence of 7%-9%; patients who had a Billroth II resection for stomach ulcers had an incidence of 13%-16%. An SCa incidence of 10.7% was found in stomach ulcer patients who were treated conservatively, without surgery. A similar incidence was found for patients with chronic atrophic gastritis, who were observed for only 10-15 yr after surgery. There are no studies in which conservatively treated patients with duodenal ulcers were followed for a sufficient time (30 yr). Although rats subjected to Billroth II resection have an SCa incidence of 35%-40%, vs 0% in controls, the results of these animal studies are not directly applicable to humans. In the rat studies, healthy gastric tissue is suddenly placed in an unphysiologic position,

while in ulcer patients the mucosa is abnormal before surgery. Furthermore, the growth behavior of rat SCa differs from that of human SCa. The latter rarely infiltrates the jejunum but it does metastasize, unlike rat SCa. This review shows that Billroth II resection without enteroanastomosis in ulcer patients does not cause a markedly higher incidence of SCa compared with that found in similar ulcer patients treated without surgery. 79-1875 Heredity and Gastrointestinal Tract Cancer. (Eng) Lynch, H. T. (Dept. Preventive Medicine/Public Health, Creighton Univ. Sch. Medicine, Omaha, NE, 68178); Lynch, P. M. In: *Gastrointestinal Tract Cancer*. Lipkin, M.; Good, R. A., eds. (New York, London: Plenum Medical Book Co.): Sloan Kettering Inst. Cancer Series 602 pp.; pp. 241-274; 1978.

The role of genetic factors in the etiology of gastrointestinal (GI) tract cancers is surveyed. Environmental factors appear to be responsible for most malignant neoplasms of the oral cavity, esophagus, liver, and pancreas. However, there is convincing evidence that hereditary factors play a role in tylosis palmaris et plantaris, hereditary pancreatitis, and autosomal dominantly inherited conditions predisposing to esophageal and pancreatic carcinoma. Certain remarkable kindreds such as those exhibiting ataxia-telangiectasia have an identifiable gastric cancer association. Others have manifested gastric carcinoma through multiple generations, with evidence of immunodeficiency being present in high-risk relatives. Additional traits or diseases that have been associated with gastric cancer in the general population include blood group A, pernicious anemia, atrophic gastritis, and achlorhydria, each of which appears to have a familial or genetic component. Autosomal dominantly inherited Peutz-Jeghers syndrome and celiac disease appear to predispose to cancer of the small intestine and possibly other anatomical sites. Colon cancer susceptibility has been associated with familial polyposis coli, Gardner's syndrome, Turcot's syndrome, and generalized GI polyposis. Although a few primary genetic associations have been described in the GI system, the variable interaction of environmental and genetic factors undoubtedly influences cancer frequency. (170 refs)

79-1876 Primary Lymphomas of the Gastrointestinal Tract. I. Plasma Cell Tumors. (Fre) Henry, K. (No affiliation given); Farrer-Brown, G. *Gastroenterol Clin Biol* 2(12): 1058-1059; 1978.

A previously published article concerning a series of 125 patients with lymphomas of the gastrointestinal tract is reviewed briefly. This series was the first to have a significant percentage of plasmacytomas (49%) among gastrointestinal lymphomas. (13 refs)

- 79-1877 The Transformation Zone.** (Eng) Coppleson, M. (King George V. Hosp., Sydney, Australia). In: *Cervical Pathology and Colposcopy. Selected Papers from the Second World Congress of Cervical Pathology and Colposcopy held in Graz, Austria, 15-18 October 1975.* Burghardt, E.; Holzer, E.; Jordan, J. A., eds. (Stuttgart: Georg Thieme Publishers): 146 pp.; 78-80; 1978.

Exposure of ectocervical columnar epithelium to the lower pH of the vagina that occurs at birth, during menarche, or during the first pregnancy results in squamous metaplasia; the end result is a typical or an atypical transformation zone. The former is first seen colposcopically as a fusion of preexisting columnar-epithelial-covered villi with persistence of its dissected surface contours; later, the surface is flattened. White epithelium, punctation, mosaic, atypical vessels, leukoplakia, increased nuclear density, abnormal intraepithelial capillaries, or a keratin covering may be observed in an atypical transformation zone, the site of dysplasia and preclinical carcinoma. (no refs)

- 79-1878 Teratomas and Chimeras.** (Eng) Illmensee, K. (No affiliation given); Stevens, L. C. *Sci Am* 240(4): 120-132; 1979.

Teratomas originate from germ cells and are composed of neoplastic cells plus many kinds of differentiated cells and tissues at various stages of maturation. Teratomas that contain embryonal carcinoma cells continue to grow and are malignant (teratocarcinomas), but those in which the embryonal cells differentiate into various kinds of normal tissue are benign. The malignant stem cells can differentiate normally in the mouse embryo and give rise to chimeras, or genetic mosaics. (no refs)

- 79-1879 Is the Role of the Environment in Carcinogenesis Overestimated?** (Eng) Calabrese, E. J. (Div. Public Health, Univ. Massachusetts, Amherst, MA, 01003). *Med Hypotheses* 5(1): 5-14; 1979.

The role of environmental factors in carcinogenesis is critically reviewed. Despite the fact that environmental factors may initiate and/or promote carcinogenesis, the claim that 85%-90% of all cancers are environmentally related, while probably accurate, is misleading because it neglects the role of the individual's health status as influenced by genetic and nutritional factors. For example, certain racial groups, particularly those of Celtic origin, are significantly more predisposed to the development of UV-induced skin cancer than other whites. Toxicological evidence supports the position that a person's genotype plays a potentially important role in modifying one's susceptibility to arylamine-induced bladder cancer. There also appear to be differences in individual susceptibility to aromatic hydrocarbon-induced bronchogenic carcinoma. Individuals whose lymphocytes metabolize

benzo(a)pyrene via arylhydrocarbon hydroxylase at a high rate following exposure to inducers are suspected of having an increased risk of lung cancer development following long-term exposure to cigarette smoke. Dietary deficiencies of vitamin A and riboflavin have been shown to enhance the development of epithelial cancers in animals exposed to carcinogenic aromatic hydrocarbons. Various epidemiological studies have demonstrated the existence of an inverse association between the incidence of gastric cancer and the consumption of food high in vitamin C. It thus appears that an individual's adaptive capacity may be a critical factor affecting the development of certain environmentally related cancers. (61 refs)

- 79-1880 Mortality for Cancer of the Corpus Uteri (2 Letters to Editor).** (Eng) Miller, A. B. (NCIC Epidemiology Unit, Univ. Toronto, Toronto, Ontario, Canada). *Can Med Assoc J* (11): 1275-1276; 1978.

The importance of distinguishing clearly between cancer of the corpus uteri and cervical cancer so that trends in incidence and mortality can be accurately assessed is discussed in a letter of comment and in a letter of response. Data collection methodologies in three Canadian provinces and some of the resulting data are summarized, and a plea for unambiguous recording of the cause of death is made. (7 refs)

- 79-1881 Current Concepts on the Histogenesis, Pathology, and Immunochemistry of Germ Cell Tumors of the Testis.** (Eng) Nochomovitz, L. E. (No affiliation given.); Rosai, J. *Pathol Annu* 13(1): 327-362; 1978.

The pathology and immunochemistry of germ cell tumors of the testis are reviewed. Classical seminoma accounts for 30%-40% of testicular neoplasms. Morphologically, it is composed of sheets of uniform polyhedral cells segregated into compartments by slender fibrous septa containing a lymphocytic infiltrate. Spermatocytic seminoma is a rare tumor that usually occurs in older men. The tumor cells form sheets without segregation into compartments. Embryonal carcinoma, which constitutes about 20% of all testicular tumors and occurs most frequently in the third decade of life, has a tendency to metastasize widely. Adult teratoma represents 5%-10% of testicular neoplasms. In spite of its benign histologic appearance, it can metastasize and cause death. Mature cartilage and smooth muscle are frequently seen, and the cysts are lined by alimentary, respiratory, or squamous epithelium. Teratocarcinoma, which accounts for 20%-30% of testicular tumors, is distinguished from adult teratoma by the presence of malignant elements in addition to fully differentiated tissue. Choriocarcinoma, which is highly malignant, is usually present as a component of a larger germ cell tumor. It consists of bizarre multinucleated syncytiotrophoblastic cells intermingled with compact sheets of cytotrophoblastic cells. Yolk sac tumor of the testis usually occurs in infants

and children < 3.5 yr of age. Its microscopic pattern reflects elements of the differentiating yolk sac. Elevated levels of α -fetoprotein and β -human chorionic gonadotropin have been detected in patients with nonseminomatous germ cell tumors. Germ cell tumors spread mainly by lymphatics to the common iliac and paraaortic lymph nodes. (155 refs)

- 79-1882 Irradiation Related Thyroid Cancer: History and Current Recommendations.** (Eng) Stockwell, R. M. (Univ. Connecticut Sch. Medicine, Farmington, CT). *Conn Med* 43(2): 63-67; 1979.

The origin and historical development of irradiation as a treatment for benign diseases of the thymus, head, and neck and the relationship of this therapy to thyroid cancer are reviewed. (17 refs)

- 79-1883 Unit of Epidemiology and Biostatistics.** (Eng) Muir, C. S. (International Agency Res. Cancer, Lyon, France). *IARC Annual Report* 19-43; 1978.

A progress report on various areas of research conducted by the Unit of Epidemiology and Biostatistics of the International Agency for Research on Cancer is presented. The Agency continues to play a coordinating role in the field of descriptive epidemiology. The aim of the program of descriptive epidemiology is to map the occurrence of cancer throughout the world and to improve the comparability of incidence data. The existence of differences in cancer risk in different populations facilitates the formulation and testing of etiological hypotheses by the Agency and other bodies. The search for etiological factors in esophageal cancer continues, particularly in the Caspian littoral of Iran and in Normandy. The Unit also is coordinating an extensive series of international studies to explore the role of alcoholic beverages in neoplasia. These studies are currently being extended to Switzerland and Belgium. An international case-control study of the roles of tobacco, alcohol, and occupation in laryngeal cancer has been undertaken. Reasons for the high lung cancer mortality in Cuban women are also being examined by a case-control study, and studies of lung cancer in Cantonese women continue. The effects of diet on colon cancer are being evaluated in Denmark and Finland. The occupational carcinogenesis study program has been expanded. The biostatistical section is evaluating the efficacy of screening programs for the early detection of cervical cancer in relation to mortality and optimum screening intervals. A monograph on modern techniques in the analysis of case-control studies is near completion. (42 refs)

- 79-1884 Epidemiological Identification of Cancer Hazards.** (Eng) Muir, C. S. (Unit Epidemiology and Biostatistics, International Agency Res. Cancer, Lyons,

France). In: *Prevention and Detection of Cancer. Part II. Detection. Vol. 1 High Risk Markers. Detection Methods and Management.* Neiburgs, H. E., ed. (Marcel Dekker, Inc.: New York): 1299 pp.; 3-23; 1978.

Epidemiologic approaches to the identification of cancer hazards are reviewed. As a basis on which to formulate hypotheses, the epidemiologist can examine the behavior of the disease itself with regard to age and sex patterns, geographical distribution between and within countries, variations in histologic type, changes over time and in migrant populations, and clinical observations. These data can then be used to formulate a hypothesis that can be tested by epidemiologic techniques, including case/control and prospective studies. Examples of these techniques are presented. The results of epidemiologic studies have shown that the majority of human cancers are probably due to environmental agents, acting singly or in combination. These agents are of two major types: powerful carcinogens acting on a relatively small number of workers and with generally unknown significance for the general population; and widely distributed agents such as tobacco smoke and excessive exposure to sunlight, over which there is a large measure of personal control. With regard to prevention of carcinogenesis by these agents, much has to be done by the government to protect worker and community. (37 refs)

- 79-1885 The Digestive Form of α -Chain Disease.** (Eng) Seligmann, M. (Lab. Immunochemistry and Immunopathology--INSERM U 108, Res. Inst. Blood Diseases, Hopital Saint-Louis, Paris 10, France); Rambaud, J. C. In: *Gastrointestinal Tract Cancer.* Lipkin, M.; Good, R. A., eds. (New York, London: Plenum Medical Book Co.): Sloan Kettering Inst. Cancer Series 602 pp.; pp. 119-141; 1978.

The epidemiology, clinical features, pathology, immunochemical diagnosis, course, treatment, and pathogenesis of digestive α -chain disease are reviewed, together with the results of structural and cellular studies of the immunoglobulin (Ig) abnormality and the relationship between this disease and "Mediterranean lymphoma." α -Chain disease is a proliferative disorder of B-lymphoid cells involving primarily the IgA secretory system, in which plasma cells produce a presumably homogeneous population of Ig molecules consisting of incomplete α chains devoid of light chains. Most affected patients are between 10 and 30 yr old. The digestive form is rare in developed countries. The disease is usually revealed by severe malabsorption syndrome. The intestinal lesions usually predominate in the duodenum and jejunum, and they are characterized by plasma cell infiltration. The diagnosis is usually suspected or established by immunoelectrophoretic analysis of the serum proteins. There appears to be an early premalignant stage of the digestive form of α -chain disease that progresses to a fatal malignancy. The frequency of this disease among populations exposed to conditions of poor hygiene and the evidence for complete remissions induced in the early stage by po antibiotic therapy implicate environmental

factors in the pathogenesis of the disorder. The evidence suggests that α -chain disease probably represents a model of a lymphoma characterized by a continuous sequence of events ranging from an apparently benign hyperplastic process to overt neoplastic proliferation. Analysis of the sequence of events occurring between the premalignant and malignant stages may offer insight into the development of lymphomas in humans. (62 refs)

- 79-1886 Epidemiology of Esophageal Cancer.** (Eng) Haas, J. F. (Cornell Univ. Medical Coll., New York, NY, 10021); Schottenfeld, D. In: *Gastrointestinal Tract Cancer*. Lipkin, M.; Good, R. A., eds. (New York, London: Plenum Medical Book Co.): Sloan Kettering Inst. Cancer Series 602 pp.; pp. 145-172; 1978.

The geographical pathology, demographic characteristics, and etiology of esophageal cancer (EC) are reviewed. Dramatically different patterns of occurrence are observed for EC in different parts of the world, among different ethnic groups, and in men and women. There is no unifying hypothesis to explain the varied epidemiological picture presented by EC in different regions of the world. This picture suggests that there is more than one environmental determinant. Alcohol apparently plays a role in the development of EC, particularly in North America and Europe, although there is no evidence that it acts directly as a carcinogen. Tobacco smoking, closely tied with alcohol consumption, seems to make an independent contribution to EC. Smoking induces dose-related histological changes in the esophageal squamous epithelium that are strongly reminiscent of those preceding bronchogenic carcinoma. In areas such as the Caspian littoral, where EC is not tobacco- or alcohol-related, dietary factors are of special concern. Geophysical environment may be reflected in the effect of local soil characteristics on diet. Molds productive of carcinogens could be geographically limited food contaminants. Mucosa conditioned by chronic specific nutritional deficiency may be especially vulnerable to the action of carcinogens. (106 refs)

- 79-1887 Bronchopulmonary Tumors: Epidemiology.** (Ita) Renga, G. (Istituto di Igiene, Università degli Studi di Ancona, Ancona, Italy). *Minerva Med* 70(3): 173-194; 1979.

Epidemiological and etiological data on lung cancer are reviewed. In Europe, lung cancer mortality is $> 100/100,000$ in England; $61-99/100,000$ in Germany, Switzerland, Austria, Denmark, Netherlands, Belgium, and Finland; $31-60/100,000$ in Poland, Bulgaria, Greece, Hungary, Italy, France, Ireland, and Sweden; and $16-30/100,000$ in Yugoslavia, Spain, Portugal, Romania, Norway, and Iceland. In Italy, a positive correlation was found between the size of a city in terms of population and lung cancer mortality. Air pollution, occupational exposure to harmful substances, and

smoking are considered the principal environmental factors of lung cancer. Industrial pollutants suspected of inducing lung cancer in humans include uranium, radon, hematite, polycyclic aromatic hydrocarbons, asbestos, arsenic, chromium, nickel, mustard gas, acrylonitrile, chloromethyl ether, and, possibly, beryllium and vinyl chloride. Carcinogens detected in tobacco smoke include dimethylnitrosamine, diethylnitrosamine, methylethylnitrosamine, N-nitrosopyrrolidine, nitrosopiperidine, benzo(a)pyrene, methylbenzo(a)pyrene, dibenzoacridine, dibenzocarbazole, β -naphthylamine, benzo(a)fluoranthene, methylfluoranthene, benzantracene, chrysene, nitrosoanabasine, benzophenanthrene, nitrosonornicotine, polonium-210, and arsenic. (55 refs)

- 79-1888 The Natural History of Lung Cancer: A Review Based on Rates of Tumour Growth.** (Eng) Geddes, D. M. (Brompton Hosp., London, England). *Br J Dis Chest* 73(1): 1-17; 1979.

The natural history of lung cancer is formulated based on a review of tumor growth rates. The exponential model of tumor growth, which predicts that tumor doubling goes on at a constant rate, fits the observed facts reasonably well. To calculate the natural history of a solid tumor that grows exponentially, the doubling time, size at diagnosis, and total tumor mass at death need to be known. Pooling the doubling times of lung cancer reported in the literature, the time from malignant change to diagnosis is calculated to be approx 10 yr and, following diagnosis, the av time to death is approx 18 mo. Predicted survival curves were calculated from time of diagnosis for different-sized tumors based on the distribution of their doubling times. The curves for different histological types of tumors show marked differences, with adenocarcinoma patients surviving longer than those with squamous tumors. The natural history calculated according to this model correlates well with several clinical observations. The long delay between the start of smoking and the appearance of lung cancer suggests that prolonged stimulation is necessary or that there is some efficient anti-tumor defense system that becomes less effective with age. The 5-yr survival in lung cancer varies from 5% to 9%, a range similar to that predicted from growth rates. Earlier diagnosis and treatment are not likely to influence lung cancer survival rates to any great extent. (32 refs)

- 79-1889 Epidemiology of Gastric Cancer.** (Eng) Haas, J. F. (Cornell Univ. Medical Coll., New York, NY, 10021); Schottenfeld, D. In: *Gastrointestinal Tract Cancer*. Lipkin, M.; Good, R. A., eds. (New York, London: Plenum Medical Book Co.): Sloan Kettering Inst. Cancer Series 602 pp.; pp. 173-206; 1978.

The epidemiology of gastric cancer (GC) is reviewed, with regard to pathology, relation to gastric polyps, time trends, personal risk factors, racial and ethnic differences in distribu-

tion in the US, nativity and migrant studies, social class and occupational factors, familial and hereditary influences, pathogenesis and etiology and models of its etiology. A precipitous decline in death rates from GC has occurred at a time of slowly rising mortality from all cancers. GC frequency varies dramatically throughout the world. Two highly industrialized societies, Japan and the US, are near the top and bottom, respectively, of the rank order of GC mortality by country. Similarly, Chile and Mexico, although only modestly industrialized, show a fivefold difference in GC mortality. Even within countries with uniform reporting and classification systems, GC mortality may show marked differences from area to area. GC is more frequent in men than in women in all settings, and its incidence and mortality rates rise steeply with age. The importance of racial differences in susceptibility to GC is unclear. Migrant studies indicate that persons moving from high- to low-risk areas retain a considerable excess risk compared with natives of low-risk areas. GC risk is greatest among the poor. For metal workers, miners, rubber workers, and workers exposed to wood dusts and asbestos, there is evidence that specific occupational hazards may exist for GC. Epidemiological investigations of the pathogenesis and etiology of GC have suggested links between this disease and blood group, pernicious anemia, intestinal metaplasia, and diet (including exposure to nitrosamines and polycyclic hydrocarbons). Recent efforts to consolidate information on GC into an etiological model have concentrated on mechanisms by which the mucous barrier of the stomach might be damaged, exposing the epithelium to carcinogens. (117 refs)

- 79-1890** **Ulcerative Colitis and Colon Cancer.** (Swe)
Brostrom, O. (Gastroenterologiska sektionen, Sodersjukhuset, Stockholm, Sweden); Nystrom, B.; Reichard, H.; Ost, A. *Lakartidningen* 76(3): 99-100; 1979.

Studies of the relationship between ulcerative colitis and colon cancer are reviewed. The incidence of colon cancer is relatively low among ulcerative colitis patients, with cancer developing most often before age 50 yr. Seven cases of colon cancer were found in a series of 220 patients with ulcerative colitis diagnosed during 1945-1964 and followed until 1975. Colon cancer can be prevented by proctocolectomy, but this procedure should be restricted to patients at risk. Risk factors for colon cancer in ulcerative colitis are total colitis; chronic, continuous colitis as opposed to an intermittent course; duration of colitis > 10 yr; and, possibly, onset of colitis at a young age. In a prospective epidemiological study, the incidence of colon cancer was 0/229 patients with total colitis lasting < 10 yr, 2/392 combined observation years (COR) among patients with colitis > 11-20 yr, and 3/181 COR among patients with colitis > 20 yr. (9 refs)

- 79-1891** **Epidemiology of Colorectal Cancer.** (Eng)
Schottenfeld, D. (Dept. Epidemiology and Pre-

ventive Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Haas, J. F. In: *Gastrointestinal Tract Cancer*. Lipkin, M.; Good, R. A., eds. (New York, London: Plenum Medical Book Co.); Sloan Kettering Inst. Cancer Series 602 pp.; pp. 207-240; 1978.

The epidemiology of colorectal cancer is reviewed. Colorectal cancer is the most common newly diagnosed malignancy in the US. Adenocarcinomas are overwhelmingly the most prevalent histological type; histological subgroups of mucin-producing tumors may be of both etiological and prognostic importance. The ratio of colon cancer (CC) to rectal cancer (RC) incidence rates is correlated with overall incidence of large intestine cancer. The proportion of CC's is highest in high-incidence areas. Where the rates for both tumors are low, the proportion of RC's is relatively high. Even within countries, marked variation may occur in the frequency of cancers of the large intestine. Countries subject to a high incidence of CC demonstrate a relatively higher frequency of sigmoid cancers, whereas in low-risk countries cancers of the cecum and ascending colon predominate. The age-specific incidence rates of both CC and RC rise steadily from ages 10-14 to 80-84. RC is more prevalent among men in most countries, whereas CC affects both sexes at similar rates. Differences between US whites and nonwhites with respect to CC mortality were marked before 1950, but subsequent years have seen a steady convergence as a result of increasing rates among nonwhites. Migration studies have suggested that environmental influences later in life can affect the risk of CC. Studies in Japan, Colombia, and the US demonstrated a higher CC incidence among the upper social classes. Diseases that may be associated with large intestine cancer include ulcerative colitis and Crohn's disease. There is also an apparent association with diseases causing the development of adenomatous polyps in the colon and rectum. Possible dietary factors that contribute to colorectal cancer include reduced fiber intake and increased meat consumption. Studies concerning the effects of these and other dietary factors on intestinal microflora and metabolism are reported. (89 refs)

- 79-1892** **The Epidemiologic Approach to the Evaluation of Organics in Drinking Water.** (Eng) Cantor, K. P. (U.S. Environmental Protection Agency, Cincinnati, OH, 45268); McCabe, L. J. *Water Chlorination* 2: 379-393; 1978.

Epidemiologic methods of evaluating the cancer hazard posed by contaminants in drinking water are reviewed, as are some studies that have utilized these methods. The hypotheses upon which a study may be based may originate from laboratory experiments combined with information on environmental exposures to humans, the observations of astute clinicians, and geographical and temporal comparisons of the rates of exposure and disease in human populations. Ecologic studies, which correlate the geographical distribution of disease with environmental factors, are relatively inexpensive and can be completed quickly. However, they have only a

limited ability to take account of possible confounding factors and should be used only to provide qualitative guides to risks. Case-control and cohort studies are valuable in testing hypotheses and in developing quantitative estimates of health risks related to particular exposures or personal characteristics. They are, however, more costly and time-consuming than ecologic studies. Several ecologic studies have investigated the potential cancer risk associated with chlorination and/or organics in drinking water supplies. Bladder and colon/rectal cancer mortality was correlated with the water quality parameter in several of these studies. Analytic studies based on information from cancer patients and appropriately matched controls are now imperative to evaluate a possible causal relationship. (23 refs)

- 79-1893 Epidemiology of Carcinoma of the Cervix.** (Eng) Miller, A. B. (Epidemiology Unit, Natl. Cancer Inst. Canada, Dept. Preventive Medicine and Biostatistics, Univ. Toronto, 121 St. Joseph St., Toronto, Ontario, M5S 2R9, Canada). In: *Cervical Pathology and Colposcopy. Selected Papers from the Second World Congress of Cervical Pathology and Colposcopy held in Graz, Austria, 15-18 October 1975*. Burghardt, E.; Holzer, E.; Jordan, J. A., eds. (Stuttgart: Georg Thieme Publishers): 146 pp.; 103-111; 1978.

Epidemiological studies of carcinoma of the cervix are reviewed. In practice, carcinoma of the cervix has been shown to have a higher incidence in urban populations than in rural populations, in the lower social classes than in the upper social classes, in Negroes in the US than in whites, in married women than in single women, in widowed or divorced women than in married women, in multiparas than in nulliparas, in women married early than in those married later, in women with a first pregnancy at a young age than in those with first pregnancy at an older age, in those who were sexually initiated in adolescence than in those who were initiated after adolescence, in women with a history of syphilis than in those without such a history, and in those with several sexual partners than in those with only one partner. The correlation for some of these variables is highly significant. The effects of age at first marriage and age at first pregnancy disappear when the data are controlled for age at first intercourse. There is also a body of evidence that suggests that herpes virus type 2, which is primarily transmitted by sexual contact, may be etiologically related to carcinoma of the cervix. Some

variables that have been suspected as being associated with a higher incidence of carcinoma of the cervix are clearly not related when a number of studies are considered. Such variables include coital frequency, mean age at menarche, contraceptive practices, and partner not circumcised. (11 refs)

- 79-1894 Causes of Cancer (Letter to Editor).** (Eng) Peto, R. (Radcliffe Infirmary, Oxford, England). *Nature* 277(5696): 428; 1979.

The claim that many, and perhaps most, cancers are caused by certain sexual habits, smoking, and diet rather than by environmental pollutants is substantiated. Smoking is responsible for about 30% of all British cancer deaths. Uterine cervical cancer is much more common in prostitutes than in nuns, and it is commoner among women who have had many sexual partners or who begin intercourse at an early age. Carcinogenesis in rats pretreated with carcinogens is affected by increases or decreases in certain dietary fats, and fat consumption in humans has been related to the development of colon and breast cancer. (4 refs)

- 79-1895 Industrial Cancer--Whose Responsibility?** (Eng) Alderson, M. (Inst. Cancer Res., Sutton, Surrey, England). *Ann Occup Hyg* 21(3): 285-291; 1978.

The problems of industrial cancer and its control are surveyed. Cancer control depends on the collaboration of central government, industry, unions, medical personnel, research teams, and the general public. Research studies should be based on the best hypotheses derived from clinical experience, laboratory investigations, and epidemiology. After research has demonstrated and quantified a risk, plans must be laid for preventing further disease. In this, the advantages of control must be balanced against economic and other hardships caused by stringent regulation of the use of a particular substance. Primary prevention aims at removing the carcinogenic agent or reducing exposure, whereas secondary prevention aims at identifying disease at a stage at which treatment can be applied and will be successful. The latter must be considered whenever a long-standing hazard has been identified. It should involve both screening for disease and education of exposed workers. (15 refs)

CHEMICAL CARCINOGENESIS

- 79-1896 **Chemical Carcinogenesis: Dose-Response Extrapolation (Letter to Editor).** (Eng) Clayson, D. B. (Office Deputy Director, Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE, 68105). *Science* 203(4385): 1068-1069; 1979.

In dose-response extrapolation, the further one extrapolates from the data base, the greater the level of uncertainty in the predictions. In cancer induction, the uncertainties in extrapolation are compounded by the complexity of the process and the vast number of factors, such as promoting agents, that may drastically affect tumor yield. The official establishment of asbestos dust standards in 1969, following recommendations of the British Occupational Hygiene Society, was based on information that was inadequate as the justification for setting an officially approved 'safe' asbestos level. This conclusion has since been reached by the Health and Safety Executive Advisory Committee on Asbestos as well. (1 ref)

- 79-1899 **The Routine Monitoring of Airborne Asbestos in an Occupational Environment.** (Eng) Richards, A. L. (TBA Industrial Products Ltd., T & N Ltd., P.O. Box 22, Trafford Park, Manchester, England). *Ann Occup Hyg* 21(3): 315-322; 1978.

Techniques and strategy used in the routine monitoring of airborne asbestos in a major asbestos textile factory employing approx 1,500 persons are described. It was possible to assess the biological effects of asbestos by personal membrane-filter sampling, to control the general factory environment with the use of particle counters, and to study working practices with both measuring techniques. (3 refs)

- 79-1900 **Nucleic Acid Metabolism in the Rat Following Short-Term and Prolonged Ingestion of Chrysotile Asbestos or Cigarette-Smoke Condensate.** (Eng) Jacobs, R. (Dept. Biochemistry, Univ. Coll., P.O. Box 78, Cardiff CL1 1XL, Wales); Weinzwieg, M.; Dodgson, K. S.; Richards, R. J. *Br J Exp Pathol* 59(6): 594-600; 1978.

The effects of chrysotile asbestos or cigarette smoke condensate ingestion on DNA and RNA metabolism were studied in various tissues of 3-mo-old male MRC hooded rats. The rats received asbestos (50 mg/day) for 1 wk or for 5-15 mo. Rats treated for either the short- or long-term periods showed statistically significant increases in [³H]thymidine incorporation into DNA in the small intestinal mucosa, colon, rectum, and stomach, and spleen and a significant decrease in the incorporation of this radiolabel into liver DNA. Short-term asbestos ingestion did not affect [³H]uridine incorporation into RNA of any tissue, but long-term treatment significantly increased incorporation in lung RNA and decreased incorporation in liver RNA. Short-term ingestion of a diet containing cigarette smoke condensate produced significant increases in [³H]uridine incorporation into RNA in the small intestinal mucosa, submucosa, spleen, and heart. Long-term ingestion of this diet produced similar changes in the submucosa, spleen, and lung. It is concluded that the apparent specificity and the mechanism(s) whereby ingested asbestos induces changes in nucleic acid metabolism require further experimentation. (27 refs)

- 79-1903 **An Autopsy Case of Pulmonary Asbestosis, Peritoneal Mesothelioma, and Incidental Stomach Cancer.** (Jpn) Hiasa, Y. (Dept. Pathology, Nara Medical

Univ., Nara, Japan); Ohjima, M.; Iwata, M.; Miyadai, A.; Yagai, R.; Murata, Y.; Yamada, K.; Ozono, S.; Shimamoto, K.; Tsujimoto, H.; Okajima, E. *Gan No Rinsho* 25(2): 124-132; 1979.

The case report of a 62-yr-old man who, upon autopsy examination, was found to have pulmonary asbestosis, peritoneal mesothelioma, and stomach cancer is presented, and literature concerning mesothelioma patients is reviewed. The man had worked in an asbestos plant for about 30 yr, had been a moderately heavy smoker (1 pack/day), and had a history of tracheal inflammation (cough and expectoration) since the age of 45. The patient was first treated for prostatic concretions. Complaints of stomach pain 3 mo later led to a diagnosis 2 mo later of adenocarcinoma of the jejunum. The patient died shortly thereafter. Autopsy revealed a sheet of gray-white tumor covering the serosal surface of the large bowel and stomach but not involving the mucosa. The inferior side of the diaphragm was covered with tumors. Histological studies showed mesothelioma and an incidental stomach adenocarcinoma. Microscopically, numerous asbestos bodies were found within fibrous areas in the alveolar walls and in the smaller bronchial branches. The literature showed that asbestosis was associated with 22/26 pleural mesothelioma cases and 5/7 peritoneal mesothelioma cases. (25 refs)

79-1904 Correlation Between Iron-induced Lipoperoxidation and "Unscheduled" DNA Synthesis in Isolated Nuclei and Cultured Hepatocytes (Meeting Abstract). (Eng) Shires, T. K. (Dept. Pharmacology, Univ. Iowa, Iowa City, IA, 52242); Lovig, C. *Fed Proc* 38(3, part 2): 1404; 1979. (no refs)

79-1905 Lithium Reinduction of Acute Myeloblastic Leukemia (Letter to Editor). (Eng) Orr, L. E. (Southern California Cancer Center, California Hosp. Medical Center, Los Angeles, CA, 90015); McKernan, J. F. *Lancet* 1(8113): 449-450; 1979.

The case of a patient in whom acute myeloblastic leukemia apparently was reinduced by lithium treatment is presented. Li treatment (300 mg, bid) was started for persistently low neutrophil counts and recurrent bacterial infections during the nadir of maintenance chemotherapy. Reinduction occurred 7 wk later. Li could, theoretically, have caused recruitment of granulocyte precursors from a resting to a growing state. (5 refs)

79-1909 Changes in beta-Glucuronidase Activity in WBC of Rats Exposed to Benzene, and Protective Treatment with Selenium. (Pol) Moszczynski, P. (Katedra Medycyny Pracy i Chorob Zawodowych AM, skr. poczt. 13, 30-969 Krakow, Poland); Starek, A. *Med Pr* 29(5): 379-385; 1978.

The effect of benzene inhalation (1,200 mg/m³, 6 hr/day, 6 days/wk, for 2 wk) on lysosomal β -glucuronidase (BG) activity and the protective effect of selenium pretreatment (1 or 5 μ g/kg po on 10 consecutive days) were studied in 32 male Wistar rats aged about 4 mo. Exposure to benzene alone significantly decreased BG activity in the neutrophils from 35.8 to 18.2 units ($p < 0.01$) and the lymphocyte count from 9,110/ μ l to 5,300/ μ l ($p < 0.001$), and it significantly increased the percentage of BG-positive lymphocytes from 85.9% to 93.5% ($p < 0.001$). Pretreatment with 1 μ g/kg Se failed to prevent the lymphocytopenia, but it prevented the decrease in neutrophil BG activity and the damage to the lysosomes. Pretreatment with 5 μ g/kg prevented the lymphocytopenia, increased the number of neutrophils, and prevented the decrease in neutrophil BG activity, but it increased the BG-positive lymphocyte fraction, especially lymphocytes in which the enzyme was localized in the cytoplasm. The results indicate that the lysosomal membranes of the lymphocytes were protected from the toxic effects of benzene by the smaller dose of Se, whereas both doses protected the neutrophil BG activity. - 79-1912 Effect of Dietary Fiber on Azoxymethane-induced Intestinal Carcinogenesis in Rats.** (Eng) Nigro, N. D. (Dept. Surgery, Wayne State Univ. Sch. Medicine, 540 E. Canfield Ave., Detroit, MI, 48201); Bull, A. W.; Klopfer, B. A.; Pak, M. S.; Campbell, R. L. *J Natl Cancer Inst* 62(4): 1097-1102; 1979.

The effect of alfalfa, bran, and cellulose on intestinal tumor formation and fecal biliary steroid levels was studied in male Sprague-Dawley rats treated with azoxymethane (AOM). Animals received weekly sc injections of 8 mg AOM/kg and were fed diets containing 10% fiber (wt/wt) and 35% beef fat or 20% or 30% fiber and about 6% beef fat. Control animals in each instance were fed fiber-free diets. All animals were killed after 23 wk. The addition of 10% fiber to the high-fat diet did not significantly reduce the intestinal tumor frequency (av number of tumors/rat = 7.6-9.5, vs 8.44 in fiber-free controls). However, addition of 20% or 30% fiber to the 6% fat diet significantly reduced the intestinal tumor frequency (av number of tumors/rat = 1.95-3.79, vs 4.04 in fiber-free controls). The concentration of fecal biliary steroids (mg/g dry feces) was significantly lowered in the groups with reduced tumor frequencies, whereas the total excretion of fecal biliary steroids (mg/day) did not show a similar correlation. It is suggested that intestinal tumor frequency can be reduced by increased diet fiber only when fat intake is not at a high level. The effect of fiber may be due to dilution of promoters and/or carcinogens in the intestinal tract. (16 refs)

- 79-1913 Increased Activation of Procarcinogens after Ethanol (Meeting Abstract).** (Eng) Seitz, H. K. (Veterans Admin. Hosp., Bronx, NY); Garro, A. J.; Lieber, C. S. *Fed Proc* 38(3, part 2): 1404; 1979. (no refs)

- 79-1914 Leukemia in Workers Exposed to Ethylene Oxide.** (Eng) Hogstedt, C. (Dept. Occupational Medicine, Regional Hosp., Orebro, Sweden); Malmqvist, N.; Wadman, B. *JAMA* 241(11): 1132-1133; 1979.

Between 1972 and 1977, leukemia occurred in three persons employed in a Swedish factory in which 50% ethylene oxide and 50% methyl formate were used. A 51-yr-old woman developed chronic myeloid leukemia after 4 yr exposure, a

37-yr-old woman developed acute myelogenous leukemia after 9 yr exposure, and a 56-yr-old man developed primary macroglobulinemia after an estimated exposure of 3 hr/wk for 6 yr. The 8-hr, time-weighted av concentration of ethylene oxide + methyl formate in the breathing zone of the women was calculated as 20 ± 10 ppm. Without consideration of latency time or minimum exposure, the incidence of leukemia in the factory during 1972-1977 would have been expected to be 0.2 case. The women had no known exposure to benzene, radiation, or other leukemia-inducing agents; the man had some occasional contact with benzene in laboratory work. Except for increased bleeding as the initial symptom in all three cases, there were no indications that an aplastic or hypoplastic marrow preceded the appearance of malignancy. Epidemiologic studies of larger populations exposed to ethylene oxide plus reduction of exposure through improved industrial hygiene are recommended. (14 refs)

- 79-1915 Effect of Trichloropropene Oxide and Benzo(a)fluorene on Polycyclic Hydrocarbon Carcinogenesis in C3H/He and DBA/2 Mice.** (Eng) Watanabe, M. (Res. Inst. Tuberculosis and Cancer, Tohoku Univ., Seiryomachi 4-1, Sendai 980, Japan); Watanabe, K.; Sato, H. *Gann* 70(1): 83-87; 1979.

The effects of 1,1,1-trichloropropene 2,3-oxide [TO: 1.2 micromoles (μ mol), sc] and 7,8-benzofluorene (BF: 0.6 μ mol, sc) on the induction of sc fibrosarcoma by 3-methylcholanthrene (3-MC: 0.6 μ mol, sc) and benzo(a)pyrene (BP: 0.6 μ mol, sc) were studied in C3H/He and DBA/2 mice. The chemicals were dissolved in corn oil or triolein and administered in a single dose. TO and, to a lesser extent, BF increased the tumor incidence in DBA/2 mice treated with BP; there was no increase in tumor incidence in DBA/2 mice treated with 3-MC. In the C3H/He mice, TO reduced tumor incidence and prolonged survival time following BP treatment, but it had no effect on tumor incidence following 3-MC treatment. BF had no effect on tumor incidence or survival time. Compared with DBA/2 mice, C3H/He mice showed a higher epidermal aryl hydrocarbon hydroxylase (AHH) activity and a higher incidence of fibrosarcomas with a reduced latency period after BP or 3-MC treatment. The carcinogenicities of BP and 3-MC were similar. Thus, the difference in sc tumor incidence in the two mouse strains may be correlated with epidermal AHH activity. (17 refs)

- 79-1916 Thiodiglycolic Acid: A Major Metabolite of Bis(2-chloroethyl)ether.** (Eng) Lingg, R. D. (Health Effects Res. Lab., U.S. Environmental Protection Agency, Cincinnati, OH, 45268); Kaylor, W. H.; Pyle, S. M.; Tardiff, R. G. *Toxicol Appl Pharmacol* 47(1): 23-34; 1979.

The major in vivo metabolites of bis(2-chloroethyl)ether (BCEE) were identified by gas chromatography/mass spectrometry following administration of a single 40 mg/kg-dose

by po gavage to male Sprague-Dawley rats. Approx 1.6% unaltered BCEE was recovered from the expired air during the first 8 hr after administration; none was recovered between 8 and 48 hr. The methyl ester/trimethylsilyl ether derivatives of the isolated urinary acid fraction yielded two metabolites: thiodiglycolic acid (TDGA) and 2-chloroethyl- β -D-glucosiduronic acid (CEGA). The av recovery of the former during the 48 hr after administration of BCEE was 33.0 mg/kg. The mass spectrum of CEGA prepared in vitro with rabbit liver microsomes was similar to that of the CEGA recovered from the urine of rats treated with BCEE, verifying CEGA as a metabolite of BCEE. (26 refs)

79-1917 Short-Term Toxicity and Reproduction Studies in Rats with Hexachloro-(1,3)-butadiene. (Eng) Harleman, J. H. (Dept. Pathology and Hygiene, Coll. Veterinary Medicine, Univ. Illinois at Urbana-Champaign, Urbana, IL, 61801); Seinen, W. *Toxicol Appl Pharmacol* 47(1): 1-14; 1979.

Wistar-derived rats were given 0.4-15.6 mg/kg/day hexachloro-(1,3)-butadiene (HCBd) by gavage for 13 wk, or 150 or 450 ppm in the diet for 2 wk. The main toxic action of HCBd was in the kidneys. Decreased urine-concentrating ability was found in females at low doses, and extensive tubular degeneration, degeneration and necrosis of individual epithelial cells, plus increased cellularity of the epithelial lining were noted in both sexes at high doses. There were no significant effects on fertility or progeny. (24 refs)

79-1918 Subcutaneous Pristane Injection Enhances the Growth of Plasma Cell Tumor MOPC-315 (Meeting Abstract). (Eng) Platika, M. (Res. Inst. Hosp. Joint Diseases, Mt. Sinai Sch. Medicine, New York, NY, 10035); Bojko, C.; Hollander, V. *Fed Proc* 38(3, part 1): 701; 1979. (no refs)

79-1919 Glycolipids as Indicators of Tumorigenesis. (Eng) Morre, D. J. (Dept. Medicinal Chemistry, Purdue Univ., West Lafayette, IN, 47907); Kloppel, T. M.; Merritt, W. D.; Keenan, T. W. *J Supramol Struct* 9(2): 157-177; 1978.

The nature of the ganglioside (GS) changes that accompany experimental liver tumorigenesis was studied in Wistar rats with hyperplastic liver nodules and hepatocellular carcinomas induced by N-2-fluorenylacetylacetamide (0.025% or 0.05% of the diet for up to 12 mo). Sialic acid and GS sialic acid values increased nearly twofold in the hyperplastic nodules and reached max levels in poorly differentiated, well-circumscribed hepatomas. The levels were also elevated in carcinogen-treated animals before the appearance of nodules or hepatoma and in the apparently normal livers of

rats with transplanted sc hepatomas. The alterations in glycolipid composition appeared to be directly related to alterations in biosynthetic activities. The pattern during tumorigenesis was the inverse of that during normal development. Also, GS patterns showed a progressive simplification from hyperplastic nodules to well-differentiated hepatomas and through two grades of poorly differentiated hepatomas. An increase in the activity of the branchpoint enzyme of GS biosynthesis preceded both a decrease in the branchpoint enzyme of the disialo-GS pathway and a marked increase in the galactosyltransferase of the monosialo-GS pathway. The results indicate that GS deletions are the end result of a cascade of events in malignant transformation, with the onset of GS deletions possibly correlating with the onset of malignancy. Glycolipid levels were elevated early in certain tissues surrounding the tumors, especially the blood. These findings suggest a role for GS's in cancer detection and as regulatory signals for cell growth and multiplication. (77 refs)

79-1920 Histopathologic Differences Between Nitrofen-induced and Naturally Occurring Hepatocellular Carcinomas in the B6C3F1 Mouse (Meeting Abstract). (Eng) Hoover, K. L. (Tumor Pathology Branch, NCI, Bethesda, MD, 20014); Stinson, S. F.; Ward, J. M. *Lab Invest* 40(2): 261; 1979. (no refs)

79-1921 Detection of Mutagens in the Urine of Rats Following Topical Application of Hair Dyes. (Eng) Ammenheuser, M. M. (Dept. Biology, Lamar Univ., Beaumont, TX, 77710); Warren, M. E. *Mutat Res* 66(3): 241-245; 1979.

Rats were treated with two commercial oxidative-type hair-coloring products (dyes A and B), both of which contain the direct dyes 4-nitro-o-phenylenediamine (4NOPD) and 2-nitro-p-phenylenediamine, and their urine was analyzed for the presence of mutagens with the use of *Salmonella typhimurium* strain TA1538. The study was designed to simulate actual hair-dye use conditions. From 10 to 30 ml of dye A or B + an equal volume of hydrogen peroxide were applied to shortened hair on the back of the rat, allowed to remain for 20 min, and then removed by shampooing and thorough rinsing. Urine specimens were collected every 24 hr for 4 days. The same procedure was used for a soln of 120 mg 4NOPD in acetone or isopropanol (IP). Rats were also inoculated ip with 5 mg 4NOPD. Mutagens were detected in rat urine after topical application and ip injection of 4NOPD. There was a fourfold increase in mutagenicity when 4NOPD was applied in acetone rather than IP, but the latter results should be more comparable to actual use conditions since IP is one of the base ingredients of hair-coloring products. The injection study indicated that only 1%-5% of the injected 4NOPD appears in the urine in a form that is directly mutagenic. Mutagens were also detected in the rat urine following application of dyes A and B. Max levels of mutagenicity oc-

curred with urine collected during the first 24 hr. Although the level of mutagenicity was low in all of the assays, a dose-response was observed when increasing volumes of mutagenic urine were tested. Urine samples collected 2-4 days after application did not show statistically significant levels of mutagenicity. The 4NOPD in the two dyes could account for at least some of the mutagenicity of the urine. A number of the other approx 24 ingredients or their reaction products could also contribute urinary mutagens, but they may not be detectable in this particular test system. They may require further metabolic activation or they may not be present in sufficient concentration. (20 refs)

- 79-1922 Neoplasms Induced in the Rat Urinary Bladder by α -Anisidine Hydrochloride (Meeting Abstract).** (Eng) Stinson, S. F. (Tumor Pathology Branch, NCI, NIH, Bethesda, MD, 20014). *Lab Invest* 40(2): 286-287; 1979. (no refs)

- 79-1923 Fluorescence Detection and Determination of Patulin by Thin-Layer Chromatography of Its Aniline Imine.** (Eng) Young, J. C. (Chemistry and Biology Res. Inst., Agriculture Canada, Ottawa, Ontario K1A 0C6, Canada). *J Environ Sci Health B* 14(1): 15-26; 1979.

A sensitive and simple procedure for patulin analysis involves extraction of patulin from the sample, silica gel column chromatographic clean-up, preparation of the aniline imine, thin-layer chromatographic separation on silica gel, hydrogen chloride hydrolysis of the imine, and fluorophore formation from the liberated aniline with fluorecamine. Limit of detection was 5 nanograms. Patulin recoveries from apple juice samples spiked at 50-500 ppb were quantitative. (24 refs)

- 79-1924 Mutagenicity of Plant Flavonols in the Salmonella/Mammalian Microsome Test. Activation of Flavonol Glycosides by Mixed Glycosidases from Rat Cecal Bacteria and Other Sources.** (Eng) Brown, J. P. (Dynapol, 1454 Page Mill Road, Palo Alto, CA, 94304); Dietrich, P. S. *Mutat Res* 66(3): 223-240; 1979.

Over 70 naturally occurring and synthetic flavonoids were screened for mutagenicity with tester strains TA1535, TA100, TA1537, TA1538, and TA98 in the Salmonella/mammalian microsome assay. Frameshift mutagenicity was confined to the flavonols (flavon-3-ols) in strains TA98, TA1537, and TA100. The two most mutagenic flavonols, quercetin (3,3',4',5,7-pentahydroxyflavone) and kaempferol (3,4',5,7-tetrahydroxyflavone), which produced 12 and 7 revertants/nanomole (nmol) in TA98, respectively, are also the most common flavonols occurring in plants. Other flavonols exhibited less activity (revertants/nmol): galangin (2.0), rhamnetin (0.45), kaempferide (0.24), fisetin (0.14), myricetin

(0.12), robinetin (0.06), and morin (0.05). All of these flavonols apparently were significantly activated by Aroclor 1254-induced rat liver microsome preparations (S9). However, subsequent study revealed that only those flavonols either lacking or possessing one B-ring OH group had an absolute requirement for microsomal activation. Alternatively, quercetin, with two B-ring OH groups, was not activated by microsomal enzymes, but by soluble (S100) enzymes from liver that are apparently constitutive and not subject to the usual chemical induction. The flavonol glycosides quercetrin (quercetin-3-O-rhamnoside), rutin (quercetin-3-O-rutinoside), and robinin (kaempferol-3-O-galactosidorhamnoside-7-O-rhamnoside) were nonmutagenic. They could, however, be activated by a variety of mixed glycosidases incorporated in the usual pour plate procedure. The most effective enzyme mixtures were obtained from rat cecal bacteria and from the snail *Helix pomatia*. (29 refs)

- 79-1927 Tissular Dynamics of the Oncofetal Markers α , Fetoprotein and γ -Glutamyl Transpeptidase in Rat Liver During Aflatoxin B₁ Induced Carcinogenesis.** (Eng) Kalengayi, M. M. (Laboratorium voor Histochemie en Cytochemie, Fakulteit Geneeskunde, Katholieke Universiteit Leuven, Leuven, Belgium); Gilli, J.; Desmet, V. J. In: *Prevention and Detection of Cancer. Part II. Detection. Vol. 1. High Risk Markers. Detection Methods and Management*. Nieburgs, H. E., ed. (New York: Marcel Dekker): 1299 pp.; 97-131; 1978.

To study the dynamics of α -fetoprotein (AFP) and γ -glutamyl transpeptidase (GGTP) in the liver during chemical hepatocarcinogenesis, male Wistar R rats were given aflatoxin B₁ (2.40 mg total dose by gastric intubation) according to three different schedules. AFP and GGTP were measured by indirect immunofluorescence (IF), double-immunodiffusion, countercurrent immunoelectrophoresis, and enzyme immunoassay (EI). During the first 10 wk of hepatocarcinogenesis, AFP levels in the drug-treated rats were significantly higher than those in the controls. The levels varied according

to the sensitivity of the detection method and the intoxication schedule. During this phase, AFP was produced by most of the transitional cells, renewed small hepatocytes, and regenerative areas, but not all of them. In contrast, GGTP activity was elevated in all proliferative areas and in every regenerative area. These changes disappeared when the carcinogen treatment was terminated. During the preneoplastic and neoplastic phases, AFP was detected only by EI and, to some extent, by IF, with only very rare nodules showing weak to moderate staining. The positive cells were arranged in trabeculae or they formed acini and tubules. Again, in contrast, a strong GGTP activity was observed in all nodules and hepatocarcinomas. The results indicate that both AFP and GGTP may be elevated in the liver before the appearance of overt hepatocarcinomas, but that GGTP is a far more sensitive marker of early, preneoplastic, and neoplastic changes than AFP. Both oncofetal markers may be useful for the study of preneoplastic and neoplastic conditions of the human liver. (61 refs)

79-1928 Aflatoxin in Peanuts: A New Approach to Consumer Protection. (Eng) Pusey, M. (Mars Ltd., Dundee Road, Slough Berks, England); Oliver, J. *Manuf Confect* 59(2): 45-47; 1979.

A new semimechanized method for analyzing aflatoxin levels in peanuts ("Aflamatic") allows faster analysis without lowering analytical standards. A 1-kg sample is taken from each ton of nuts and analyzed against a limit of 5 ppb total aflatoxins; the results for each 20-ton lot are dealt with by a strict decision-making network. The method provides a much cleaner extract, allows faster sample turnaround, and reduces the risk of cross-contamination. A schematic diagram of the Aflamatic process and a comparison of this process with two other methods are presented. (4 refs)

79-1929 Carcinogenesis by Dietary Nitrite in Experimental Animals (Meeting Abstract). (Eng) Asano, T. (Univ. Notre Dame, Notre Dame, IN, 46556). *Fed Proc* 38(3, part 2): 1451; 1979. (no refs)

79-1930 Hydrazine (Letter to Editor). (Eng) Roe, F. J. (4 Kings Road, Wimbledon, London SW19 8QN, England). *Ann Occup Hyg* 21(3): 323-326; 1978.

Data from 2/9 hydrazine manufacturers from five countries, although incomplete, provide evidence that past occupational exposures to hydrazine were not associated with any greatly increased risk of cancer. In the past, hydrazine vapor concentrations in ambient air in all nine companies were many times higher than the 0.1-ppm max that they currently claim to be achieving. Additional studies of workers in the nine companies is in progress. (12 refs)

79-1931 Carcinogenic Effects in the Syrian Golden Hamster of N-Methyl-N-formylhydrazine of the False Morel Mushroom *Gyromitra esculenta*. (Eng) Toth, B. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE, 68105); Patil, K. *J Cancer Res Clin Oncol* 93(2): 109-121; 1979.

The tumorigenicity of N-methyl-N-formylhydrazine (NMNF: administered as a 0.0078% soln in the drinking water for life beginning at 6 wk of age) in Syrian golden hamsters was investigated. Survival rates for NMNF-treated and control hamsters were similar up to 1 yr, after which survival was unexpectedly greater among the treated animals. Nineteen of 50 treated females and 24/50 treated males developed liver tumors (25 hepatomas and 18 liver cell carcinomas), 24 females and 10 males developed malignant histiocytomas, 3 females and 8 males developed gallbladder tumors (7 papillary adenomas and 4 adenocarcinomas), and 1 female and 7 males developed tumors of the bile duct (2 cholangiomas and 6 cholangiocarcinomas). None of these tumors developed in the untreated control hamsters. Other tumors occurred in low incidence and could not be attributed to treatment. In view of the demonstrated carcinogenicity of NMNF, edible false morel mushrooms, which contain substantial amounts of the compound, should not be consumed by humans. (19 refs)

79-1932 Mathematical Models of Carcinogenesis and Tumor Growth in an Experimental Rat Colon Adenocarcinoma. (Eng) Maskens, A. P. (Cancer Res. Unit, Clinique Saint-Michel, B-1040 Brussels, Belgium). In: *Gastrointestinal Tract Cancer*. Lipkin, M.; Good, R. A., eds. (New York: Plenum Medical Book Co.): Sloan Kettering Institute Cancer Series 602 pp.; 361-384; 1978.

The mathematical treatment of data for experimental rat colon adenocarcinoma systems in which drug administration schedule and rate of tumor growth and yield are interrelated is presented. This treatment proved helpful in devising models of carcinogenesis and tumor growth patterns. The biological behavior of rat colon adenocarcinomas induced by weekly treatments with 1,2-dimethylhydrazine (DMH) is characterized by three main properties. These tumors are already truly invasive carcinomas when first recognized on microscopic examination of flat mucosa; thus, no benign polyp-cancer sequence is observed. Their av growth pattern is best fitted by a Gompertz function. The doubling time is short in small lesions but progressively increases as tumors enlarge. The number of tumors per colon rises as a nonlinear function of time. Based on these findings, and on the biochemical properties of DMH and related compounds, a two-step model of carcinogenesis is proposed. It implies that each DMH treatment induces a stable and transmissible change in a number of colon epithelial cells that thereafter will be at risk for a second mutationlike event responsible for initiating cancer growth. There are several possible human implications of this model. Although colorectal polyps progress toward cancer

with variable frequency according to histologic type, some carcinomas may also arise de novo in flat mucosa. The Gompertz growth model implies that the small and, consequently, most curable tumors represent an extremely brief stage as opposed to long-lasting, slowly growing large lesions. The multistep model of carcinogenesis implies that even minimal exposures to environmental carcinogens are significant, since they could contribute to the accumulation of permanently modified cells susceptible to further malignant changes. - 79-1933 Cell Kinetics of Dimethylhydrazine(DMH)-induced Colonic Neoplasms and Their Adjacent Colonic Mucosa in the Mouse (Meeting Abstract).** (Eng) Chang, W. W. (Dept. of Anatomy, Mt. Sinai Sch. of Medicine of CUNY, New York, NY); Mak, K. M.; MacDonald, P. D. *Anat Rec* 193(3): 502; 1979. (1 ref)

- 79-1934 Immunogenicity of Chemically Induced Murine Colon Cancers.** (Eng) Belnap, L. P. (Dept. Surgery, Univ. Utah Medical Center, Salt Lake City, UT, 84111); Cleveland, P. H.; Colmerauer, M. E.; Barone, R. M.; Pilch, Y. H. *Cancer Res* 39(4): 1174-1179; 1979.

The antigenicity and immunogenicity of three colorectal carcinomas induced in female BALB/c mice by intrarectal injection of N-methyl-N-nitrosourea or by sc injection of 1,2-dimethylhydrazine (DMH) were studied. All tumors were readily transplanted. Two of these tumors (CT 26, an anaplastic carcinoma, and CT 51, a moderately well-differentiated mucinous adenocarcinoma) metastasized when transplants reached sufficient size. The third tumor (CT 36, a well-differentiated adenocarcinoma) rarely metastasized. All of the tumors were immunogenic in their strain of origin. CT 26 showed moderate immunogenicity, CT 51 weak immunogenicity. CT 36, however, was highly immunogenic, with an overall tumor incidence of 10% in immunized animals. Cross-protection experiments indicated that all tumors contained unique tumor-specific transplantation antigens. It is concluded that these three BALB/c colon carcinomas, especially CT 26 and CT 51, are excellent models for immunotherapy-chemoimmunotherapy experiments. (31 refs)

- 79-1935 Hydrazines as Mutagens in a Histidine-requiring Auxotroph of *Salmonella typhimurium*.** (Eng) Tosk, J. (American Health Foundation, Naylor Dana Inst. Disease Prevention, Valhalla, NY, 10595); Schmeltz, I.; Hoffmann, D. *Mutat Res* 66(3): 247-252; 1979.

The mutagenicity of several hydrazines (HZ's) and related compounds was tested in *Salmonella typhimurium* strain TA1530. In one series of assays, hydrazine sulfate was the most mutagenic compound tested, followed by acetylhydrazine

and 1,1-dimethylhydrazine, (DMH) Diacetylhydrazine was not mutagenic. The decrease in the number of revertants noted with higher doses of DMH may indicate an autoinhibition of mutagenicity. A similar effect in HZ mutagenicity was noted previously. Toxicity was dose-limiting for this series; ie, at higher doses, toxic effects could complicate the interpretation of the data. In another series of assays, N-aminomorpholine was the most potent HZ mutagen tested, even though it was considerably less toxic than most HZ's. Phenylhydrazine, however, was highly toxic and its mutagenicity was detected at doses that resulted in low survival of the tester organisms. The pharmaceuticals isoniazid and hydralazine were mutagenic, as were MH-30 and Royal MH, two commercial plant growth regulators formulated with maleic hydrazide. Pure maleic hydrazide was not mutagenic. The results also demonstrate the utility of strain TA1530 for determining the mutagenicity of diverse HZ's and related compounds. (13 refs)

- 79-1936 Lack of Effect of Butylated Hydroxytoluene on Dimethylhydrazine-induced Colon Carcinogenesis in Rats.** (Eng) Barbolt, T. A. (Center Experimental Pathology and Toxicology, Albany Medical Coll., Albany, NY, 12208); Abraham, R. *Experientia* 35(2): 257-258; 1979.

Male Sprague-Dawley albino rats were treated simultaneously with the antioxidant butylated hydroxytoluene (BHT: 6,600 ppm of diet) and the potent colon carcinogen dimethylhydrazine (DMH: 30 mg/kg/wk x 10 by stomach tube) to investigate the effect of these agents on colon carcinogenesis. The incidence and mean number of tumors per animal were similar to those in rats given DMH alone. Apparently, BHT did not exert any protective effect against colon carcinogenesis. (13 refs)

- 79-1937 Induction of Colonic Adenocarcinomas by 1,2-Dimethylhydrazine Intrarectally Administered in Rats.** (Eng) Markert, C. (Dept. Biochemistry, Vanderbilt Univ. Sch. Medicine, Nashville, TN); Rogers, L. W.; Chiu, J. F. *Digestion* 18(3/4): 261-265; 1978.

The carcinogenicity of intrarectally administered 1,2-dimethylhydrazine (DMH: 250 mg/kg given every third week for a total of 3 doses) was studied in Sprague-Dawley rats. The DMH-treated rats developed multiple epithelial tumors that exhibited the histologic appearance of polypoid, invasive adenocarcinomas similar to typical human colonic carcinomas. The tumors formed tubular glands lined by anaplastic columnar epithelium, a pattern that persisted in the invasive components of all tumors except one. This tumor exhibited bowel wall infiltration by randomly arranged individual tumor cells that contained copious amounts of mucin. This pattern was similar to that of human "gelatinous" or "colloid" adenocarcinomas, which are less common than the more differentiated tubular variety. The nonneoplastic

mucosa adjacent to the tumors generally exhibited increased nuclear size and decreased mucin production. (8 refs)

79-1938 Experimental Investigation on the Influence upon Chemical Carcinogenesis: 4th Communication. Influence of Different Diets on Colon Carcinogenesis by 1,2-Dimethylhydrazine in Sprague-Dawley Rats. (Eng) Schmahl, D. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Habs, M.; Wolter, S.; Kuenstler, K. *Z Krebsforsch* 93(1): 57-66; 1979.

The effect of diet on 1,2-dimethylhydrazine (DMH: 7 monthly sc injections of 30 mg/kg) carcinogenesis was studied in male and female Sprague-Dawley rats. Control rats were given a standard pelleted diet, and experimental animals were given a vegetarian diet (Diet 1), a high-fat diet (Diet 2), a high-cholesterol diet (Diet 3), or a high-carbohydrate (Diet 4). Animals given the standard diet and Diets 1-3 had a nearly 100% incidence of malignant tumors; animals given Diet 4 had a 33% malignant tumor incidence. Colon carcinomas were observed in a high percentage of animals given the standard diet (approx 63%) and Diet 1 (68%) in a lower percentage of animals given Diet 3 (53%) and Diet 2 (43%), and in comparatively few animals given Diet 4 (33%). Malignant kidney tumors were equally frequent in animals given Diets 1, 2, and 3 but much less frequent in those given Diet 4. Carcinomas of the ear duct and malignant hepatomas were found in approx equal numbers in animals of all groups. Nearly all animals given Diet 4 developed benign hepatomas and cholangiomas. Benign liver tumors were less frequent in animals given Diets 2 and 3 than in those given Diet 4 and least frequent in those given the standard diet and Diet 1. Animals given Diets 2 and 3 died earlier of malignant tumors than did those with malignant tumors given Diets 1 and 4; rats given Diet 1 had the longest survival times. Malignant tumors did not develop in animals that were not given DMH. Quantitative differences in carcinogen treatment may have been responsible for some of the differences observed in the DMH-treated animals. (10 refs)

79-1944 Arylamidation and Arylation by the Carcinogen N-2-Fluorenylacetylamine: A Sensitive and Rapid Radiochemical Assay. (Eng) Fuchs, R. P. (Groupe de Biophysique, Institut de Biologie Moleculaire et Cellulaire du CNRS, 15 rue Descartes, 67084 Strasbourg Cedex, France). *Anal Biochem* 91(2): 663-673; 1978.

A rapid and sensitive radiochemical assay that allows determination of the percentage of N-2-fluorenylacetylamine (FA) covalently bound via arylamidation or arylation is described. N-Acetoxy-N-arylacetylamines, which are generally considered the ultimate carcinogenic forms of the corresponding N-arylacetylamine, react with cellular macromolecules (nucleic acids, proteins, etc) to give arylamidation or arylation adducts. The assay is based on the difference in stability under weak alkali hydrolysis conditions (0.1 N NaOH, 75 C, 2 hr) of the specifically ¹⁴C-labeled N-acetyl group of the FA residue linked to the macromolecule via arylamidation or arylation. Native DNA that has been reacted with ¹⁴C-labeled N-acetoxy-N-2-acetylaminofluorene exhibits 16% of the fluorene adducts linked to the bases via arylation. On the other hand, denatured DNA reacts with the fluorene derivative to give almost only arylamidation adducts. (21 refs)

- 79-1946 Formation and Removal of Specific Acetylaminofluorene-DNA Adducts in Mouse and Human Cells Measured by Radioimmunoassay.** (Eng) Poirier, M. C. (In Vitro Pathogenesis Section, NCI, NIH, Bldg. 37, Room 3A19, Bethesda, MD, 20014); Dubin, M. A.; Yuspa, S. H. *Cancer Res* 39(4): 1377-1381; 1979.

Rabbit antiserum prepared against N-(guanosin-8-yl)-acetylaminofluorene was used in a radioimmunoassay (RIA) to detect the formation and removal of C-8 adducts from the DNA of cultured cells exposed to N-acetoxy-2-acetylaminofluorene (N-Ac-AAF). The assay was able to quantitate both acetylated [N-(deoxyguanosin-8-yl)-acetylaminofluorene] and deacetylated [N-(deoxyguanosin-8-yl)aminofluorene] C-8 adducts between 0.5 and 5 picomoles (pmol), but the N² adduct, 3-(deoxyguanosin-N²-yl)acetylaminofluorene, was not detected below 160 pmol. By varying the proportions of acetylated and deacetylated C-8 adducts in the RIA, a series of standard curves was developed from which the relative proportion of each adduct could be determined in unknown mixtures. DNA from mouse epidermal cells and human skin fibroblasts exposed to N-Ac-AAF in culture contained only 3% and 5%, respectively, of the acetylated C-8 adduct. Quantitation by RIA of total C-8 adducts bound to DNA yielded values 25% lower than those of total carcinogen binding determined by radiolabeling. When removal of C-8 adducts was followed over a 23-hr carcinogen-free culture period, mouse and human cells removed 40% and 50%, respectively of bound acetylated and deacetylated C-8 adducts. Preliminary evidence suggests that the rate of removal of acetylated and deacetylated C-8 adducts is similar in each cell line, since the relative amount of each adduct was the same at 1 and 24 hr. The data indicate that RIA is a sensitive and specific means of measuring carcinogen-DNA adducts. (24 refs)

- 79-1947 Metabolism of 2-Aminofluorene and 2-Acetylaminofluorene to Mutagens by Rat Hepatocyte Nuclei.** (Eng) Stout, D. L. (Dept. Anatomic and Res. Pathology, M. D. Anderson Hosp. and Tumor Inst., Univ. Texas System Cancer Center, Houston, TX, 77030); Becker, F. F. *Cancer Res* 39(4): 1168-1173; 1979.

The ability of rat hepatocyte nuclei to metabolize 2-aminofluorene (AF) and 2-acetylaminofluorene (AAF) to mutagens was studied using the *Salmonella typhimurium* mutagenicity assay. Hepatocyte nuclei produced approx 1,260% more revertants with AF than with AAF; addition of the hepatic postmitochondrial fraction (S9) to the plate produced 1,640% more mutants with AF than with AAF. Pretreatment of rats with phenobarbital (PB) or methylcholanthrene (MC) altered metabolic activity in a manner that was unique for each fraction. PB pretreatment increased the nuclear activation of A and AAF to mutagens by 400% and 460% respectively. S9 from PB-treated rats increased the nuclear AF activation by 57% and AAF activation by 125%. MC pretreatment increased the activation of AF and AAF by 69%

and 375%, respectively. S9 activation of AAF was not altered by MC pretreatment, but AF activation was increased by 41%. In rats exposed to a carcinogenic regimen of AAF in the diet, nuclear activation of AF and AAF to mutagens was increased during the first 4 wk of feeding by 28% and 85%, respectively. However, after 16 wk on the AAF diet, nuclear activation of AF and AAF had diminished by 71% and 81%. These findings indicate that rat hepatocyte nuclei can activate AF and AAF mutagens. The data also suggest that the metabolic pathways for AF and AAF activation differ and that AF may play a prominent role in mutagenesis. (21 refs)

- 79-1948 Decreased Fidelity of DNA Polymerase Activity During N-2-Fluorenylacетamide Hepatocarcinogenesis.** (Eng) Chan, J. Y. (Dept. Pathology, Section Experimental Pathology, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Becker, F. F. *Proc Natl Acad Sci USA* 76(2): 814-818; 1979.

The role of DNA synthesis during repair and the importance of DNA replication during cell division in the pathogenesis of the carcinogenic sequence led to an examination of the DNA polymerases during N-2-fluorenylacетamide (FAA)-induced hepatocarcinogenesis. α and β DNA polymerases (DNA nucleotidyltransferase; deoxynucleoside-triphosphate: DNA deoxynucleotidyltransferase) were isolated from nuclear and cytoplasmic fractions of the livers of male Sprague-Dawley rats fed FAA and from 24-hr regenerating liver. FAA was mixed with a standard synthetic diet at 0.06%. A feeding cycle consisted of 3 wk of FAA followed by 1 wk of regular meal; rats were treated with one to four cycles. The fidelity of polymerization of these enzymes was compared by determining the incorporation of noncomplementary deoxyribonucleoside triphosphates (misincorporation) on a poly(dA-dT).poly(dA-dT) template, with MnCl₂ and MgCl₂ as divalent cations. Initial studies indicated that the cytoplasmic α polymerases from carcinogen-exposed rat livers were strikingly error-prone, whereas the nuclear and cytoplasmic β polymerases retained their fidelity throughout the feeding cycles. The misincorporation was significantly accentuated by MnCl₂ compared with that obtained with MgCl₂. The products were sensitive to pancreatic DNase I digestion, indicating that the noncomplementary bases had been incorporated by the polymerization process. Nuclear α polymerase showed some degree of infidelity, but it was less than that of cytoplasmic α polymerase. (31 refs)

- 79-1949 Activation of the Carcinogen N-Hydroxy-2-acetylaminofluorene by Rat Liver Nuclei, Microsomes and Hog Liver Esterase Via Deacylation (Meeting Abstract).** (Eng) Floyd, R. A. (Oklahoma Medical Res. Foundation, Oklahoma City, OK, 73104); Steward, J. E.; Hampton, M. J.; Sridhar, R. *Fed Proc* 38(3, part 1): 658; 1979. (no refs)

- 79-1950 Acute Fine Structural Changes in Rat Hepatocytes Induced by a Single Large Dose of 2-Acetylaminofluorene.** (Eng) Flaks, B. (Dept. Pathology, Univ. Bristol Medical Sch., Bristol, England); Basley, W. A. *Virchows Arch [Cell Pathol]* 29(4): 309-320; 1979.

Electron microscopy was used to study the changes in hepatocytes from male rats given a single intragastric dose of 2-acetylaminofluorene (2-AAF: 600 mg/kg) and killed at intervals of up to 16 days after treatment. The reduction, disorganization, and degranulation of the granular endoplasmic reticulum, atrophy of the Golgi apparatus, nucleolar segregation, and lipid accumulation observed during the first 48 hr were consistent with the known activity of 2-AAF as an inhibitor of protein and RNA synthesis. Restoration of the normal morphology of the nucleoli and Golgi zones by day 5 indicated that at least partial recovery of RNA and protein synthesis had occurred. However, this recovery was accompanied by the peripheral displacement of cytoplasmic organelles by large perinuclear glycogen lakes. Cytoplasmic vacuolation of hepatocytes in the central and mid-zones of the lobules was most pronounced at day 7 when it was accompanied by scattered pyknosis. Restoration of an apparently normal liver histology was complete by day 14 after treatment. Ultrastructural changes that were observed at all stages of the experiment included alterations of granular endoplasmic reticulum and bile canaliculi, hypertrophy of the agranular endoplasmic reticulum, lipid accumulation, and increased abundance of autophagic vacuoles and residual bodies. These changes have been shown to occur during chronic exposure to 2-AAF, to become irreversible, and to be present in a variety of 2-AAF-induced hepatic cell neoplasms. The results indicate that the autoprotective effect of a high dose of a hepatotoxic agent is probably due to inhibition of protein synthesis and is analogous to cycloheximide protection. (48 refs)

- 79-1954 Dominant-Lethal Assay of Selected Cytostatics.** (Eng) Sykora, I. (Res. Inst. Pharmacy and Biochemistry, Branch Inst. Pardubice-Rosice, 533 51 Pardubice, Czechoslovakia); Gandalovicova, D. *Neoplasma* 25(5): 523-533; 1978.

The effects of various cytostatic drugs on male fertility, abortions, dominant lethal mutations, and preimplantation losses of ova were studied in S strain mice. Male fertility was significantly reduced by trichlormethinium chloride (TS-160: 1 or 5 mg/kg ip, mercaptopurine (MP: 25 mg/kg/day x 14, ip), and β -4-n-pentoxybenzoyl- β -bromoacrylic acid (Penberol: 250 mg/kg/day x 14, po). Abortions and dominant lethal mutations in the fetuses were significantly higher among females mated with males treated with cyclophosphamide (12 or 15 mg/kg/day x 14, ip; or single dose of 100 mg/kg ip), TS-160 (5 mg/kg ip), sodium bromebrate (Cytembena; 25 mg/kg/day x 14, ip), or MP. Preimplantation losses of ova were increased following treatment of male mice with TS-160, Cytembena, or MP, and fetal resorptions were increased in frequency by cyclophosphamide, TS-160, Cytembena, γ , γ -bis-4-ethylphenyl- α , β -dibromoisocrotonic acid (Edikron), and MP. In the case of Cytembena (ip) and Edikron (po), resorption was seen after treatment with lower doses of drug (10 and 100 mg/kg/day x 14, respectively) but not with the higher doses (25 and 250 mg/kg/day x 14). - 79-1956 Morphological Transformation of Hamster Embryo Cells by Cancer Chemotherapeutic Agents.** (Eng) Hirakawa, T. (Dept. Experimental Pathology, Cancer Inst., 1-37-1, Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Tanaka, M.; Takayama, S. *Toxicol Lett* 3(2): 55-60; 1979.

The abilities of various cancer chemotherapeutic agents to induce morphological transformation in hamster embryo cells were studied. The alkylating drug cyclophosphamide induced transformation at concentrations of 100-500 μ g/ml. Two other alkylating agents, N-methyl-bis(mesyloxypropyl)-amine-diphenyl-4, 4'-disulfonate and 1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea (CCNU), caused transformation at 0.5 μ g/ml, whereas carbazilquinone, methyl CCNU, and triethylenethiophosphoramidate were ineffective. Four an-

timetabolites, 6-mercaptopurine, 5-fluorouracil, cytosine arabinoside, and methotrexate, had a strong cytotoxic effect at 1 $\mu\text{g}/\text{ml}$ but did not induce morphologic transformation. The antitumor antibiotics actinomycin D, mitomycin C, and adriamycin induced transformation, whereas daunomycin, aclacinomycin A, and bleomycin were ineffective. The natural plant alkaloid vincristine caused slight transformation at 0.01 $\mu\text{g}/\text{ml}$. Most of the drugs that caused morphological transformation in vitro have been reported to be carcinogenic in vivo, whereas those that did not transform have not been shown to be carcinogenic. Thus, this in vitro assay system seems to be reliable for predicting chemical carcinogenicity. (17 refs)

- 79-1957 The Bovine Pancreas as a Model to Study Carcinogenesis (Meeting Abstract).** (Eng) Jones, R. T. (Dept. Pathology, Univ. Maryland Sch. Medicine, Baltimore, MD, 21201). *Lab Invest* 40(2): 294-295; 1979. (no refs)

- 79-1958 Syntheses of N-Alkyl-N-(hydroxy- or oxo-alkyl)nitrosamines Related to N-Butyl-N-(4-hydroxybutyl)nitrosamine, a Potent Bladder Carcinogen.** (Eng) Okada, M. (Tokyo Biochemical Res. Inst., Tokyo, Japan); Suzuki, E.; Iiyoshi, M. *Chem Pharm Bull (Tokyo)* 26(12): 3891-3896; 1978.

Thirteen N-alkyl-N-(hydroxy- or oxo-alkyl)nitrosamines structurally related to the potent bladder carcinogen N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN) were synthesized, and their carcinogenicity in rats and mutagenicity for *Salmonella typhimurium* strain TA1535 were determined. Most were prepared by nitrosation of the corresponding N-alkyl-N-(hydroxyalkyl)amine, but those with an oxo group were prepared by chromium trioxide oxidation of the corresponding N-alkyl-N-(hydroxyalkyl)nitrosamine with a secondary hydroxyl group. BBN, N-methyl-N-(4-hydroxybutyl)nitrosamine, N-ethyl-N-(4-hydroxybutyl)nitrosamine, and N-propyl-N-(4-hydroxybutyl)nitrosamine selectively induced bladder cancer in the rats; N-amyl-N-(4-hydroxybutyl)nitrosamine induced papillomas of the bladder; N-butyl-N-(2-hydroxyethyl)nitrosamine and N-ethyl-N-(2-hydroxyethyl)nitrosamine induced hepatomas and papillomas of the esophagus; N-butyl-N-(3-hydroxybutyl)nitrosamine produced degenerative changes in the liver but no tumors; N-butyl-N-(3-oxobutyl)nitrosamine, N-butyl-N-(2-oxobutyl)nitrosamine, and N-butyl-N-(2-oxopropyl)nitrosamine produced hepatomas; and *t*-BBN produced no tumors. All compounds tested except *t*-BBN were mutagenic for *S. typhimurium* with metabolic activation. (17 refs)

- 79-1959 Syntheses of N-Alkyl-N-(α -acetoxyalkyl)nitrosamines, Model Compounds for Metabolical-**

ly Activated N,N-Dialkylnitrosamines. (Eng) Mochizuki, M. (Tokyo Biochemical Res. Inst., Tokyo, Japan); Anjo, T.; Okada, M. *Chem Pharm Bull (Tokyo)* 26(12): 3905-3908; 1978.

Nine new N,N-dialkylnitrosamines monosubstituted at the α -carbon with an acetoxy group were tested for mutagenicity to *Salmonella typhimurium* strain TA1535. When N-alkyl-N-(methoxymethyl)nitrosamines were refluxed in acetic acid, they were converted into N-alkyl-N-(acetoxyethyl)nitrosamines in low but satisfactory yield. The E-Z isomer ratios of the compounds were determined by nuclear magnetic resonance analysis. N-methyl-N-(acetoxyethyl)nitrosamine, N-ethyl-N-(acetoxyethyl)nitrosamine, N-propyl-N-(acetoxyethyl)nitrosamine (PAMN), *i*-PAMN, N-butyl-N-(acetoxyethyl)nitrosamine (BAMN), *i*-BAMN, *s*-BAMN, and N-butyl-N-(1-acetoxybutyl)nitrosamine were mutagenic for *S. typhimurium* without metabolic activation. *t*-BAMN was not mutagenic in this assay. (15 refs)

- 79-1960 Syntheses of N-Alkyl-N-(ω -carboxyalkyl)nitrosamines Related to N-Butyl-N-(3-carboxypropyl)nitrosamine, Principal Urinary Metabolite of a Potent Bladder Carcinogen N-Butyl-N-(4-hydroxybutyl)nitrosamine.** (Eng) Okada, M. (Tokyo Biochemical Res. Inst., Tokyo, Japan); Suzuki, E.; Iiyoshi, M. *Chem Pharm Bull (Tokyo)* 26(12): 3909-3913; 1978.

Fourteen N-alkyl-N-(ω -carboxyalkyl)nitrosamines related to N-butyl-N-(3-carboxypropyl)nitrosamine (BCPN) the principal urinary metabolite of the potent bladder carcinogen N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN), were prepared and tested for their carcinogenicity in rats and mutagenicity in *Salmonella typhimurium* strain TA1535. Most of the compounds were synthesized by permanganate oxidation of the corresponding N-alkyl-N-(ω -hydroxyalkyl)nitrosamines. The carcinogenicity of BCPN was as great as that of BBN, and the carcinogenicity of N-ethyl-N-(3-carboxypropyl)nitrosamine (ECPN), the principal urinary metabolite of N-ethyl-N-(4-hydroxybutyl)nitrosamine, was similar to that of its parent compound. Thus, compounds with 3-carboxypropyl chains are responsible for the organospecific action of compounds with 4-hydroxybutyl groups. N-butyl-N-(carboxymethyl)nitrosamine (BCMN), a minor metabolite of BBN, was noncarcinogenic. BCPN, ECPN, N-methyl-N-(3-carboxypropyl)nitrosamine, N-propyl-N-(3-carboxypropyl)nitrosamine, N-amyl-N-(3-carboxypropyl)nitrosamine, N-butyl-N-(2-carboxyethyl)nitrosamine, and N-butyl-N-(2-hydroxy-3-carboxypropyl)nitrosamine were mutagenic for *S. typhimurium*, whereas BCMN and *t*-BCPN were not. BCPN and its homologs with 3-carboxypropyl chains did not require metabolic activation for mutagenicity. (20 refs)

79-1961 Syntheses of N-(ω -Acetoxyalkyl and ω -Carbomethoxyalkyl)-N-(α -acetoxyalkyl)nitrosamines, Model Compounds for Possible Metabolically Activated N,N-Dialkylnitrosamines. (Eng) Mochizuki, M. (Tokyo Biochemical Res. Inst., Takada 3-41-8, Toshima-ku, Tokyo 171, Japan); Anjo, T.; Okada, M. *Chem Pharm Bull (Tokyo)* 28(12): 3914-3919; 1978.

Nine new N-alkyl-N-(ω -acetoxyalkyl or ω -carbomethoxyalkyl)nitrosamines substituted at the α -carbon atom of the alkyl chain with an acetoxy group were synthesized, and they were tested for mutagenicity to *Salmonella typhimurium* strain TA1535 and other bacterial strains and for DNA-modifying effects in the *rec* assay. The compounds were N-(2-acetoxyethyl)-N-(acetoxymethyl)nitrosamine, N-(3-acetoxypropyl)-N-(acetoxymethyl)nitrosamine, N-(4-acetoxybutyl)-N-(acetoxymethyl)nitrosamine, N-(carbomethoxymethyl)-N-(acetoxymethyl)nitrosamine, N-(2-carbomethoxyethyl)-N-(acetoxymethyl)nitrosamine, N-(3-carbomethoxypropyl)-N-(acetoxymethyl)nitrosamine, N-(carbomethoxymethyl)-N-(1-acetoxybutyl)nitrosamine, N-(2-carbomethoxyethyl)-N-(1-acetoxybutyl)nitrosamine, N-(2-carbomethoxymethyl)-N-(1-acetoxybutyl)nitrosamine, and N-(3-carbomethoxypropyl)-N-(1-acetoxybutyl)nitrosamine. All nine compounds were shown to be more or less effective in the test assays. In the mutagenicity assay, they were active without metabolic activation. (19 refs)

79-1962 Maintenance in Organ Culture of Mouse Bladder Urothelium and Response to Bladder Carcinogens (Meeting Abstract). (Eng) Telang, N. T. (American Health Foundation, Naylor Dana Inst., Valhalla, NY, 10595); Hecht, S. S.; Williams, G. M. *Fed Proc* 38(3, part 2): 1074; 1979. (1 ref)

79-1963 Formation of N-Nitrosamines from Secondary Amines and Nitrite by Resting Cells of *Escherichia coli* B. (Eng) Kunisaki, N. (Dept. Enzymology, Res. Inst. for Chemobiodynamics, Chiba Univ., 1-8-1 Iohana, Chiba, Japan); Hayashi, M. *Appl Environ Microbiol* 37(2): 279-282; 1979.

Conditions for the formation of dimethylnitrosamine (DMNA) from dimethylamine (DMA) and nitrite by resting cells of *Escherichia coli* B were studied. The pH optimum for the microbial formation of DMNA was 8.0, vs a pH optimum of 3.4 (determined previously) for the chemical formation of DMNA. The formation of DMNA by *E. coli* B was proportional to incubation time and cell concentration, it did not occur when the cells were boiled before incubation, and it occurred equally well when piperidine replaced DMA as substrate. Lineweaver-Burke plots were linear up to 0.2 M DMA or 0.1 M nitrite. The reaction was inhibited at concentrations higher than 0.4 M DMA or piperidine or 0.12 M nitrite. The apparent K_m values were 0.12 M for DMA, 0.07

M for nitrite, and 0.15 M for piperidine. Cells disrupted by a French pressure cell were incapable of nitrosating DMA or piperidine, as were the supernatant and debris fractions resulting from fractionation of these cells. The results suggest that the formation of N-nitrosamine by resting cells of *E. coli* B depends on their enzyme activities. (14 refs)

79-1964 Evidence of Carcinogen-induced Replication of Partially-repaired DNA in Target Cells During Nitrosamine Carcinogenesis. (Eng) Stewart, B. W. (Sch. Pathology, Univ. New South Wales, Box 1, Kensington, New South Wales, Australia 2033); Brian, M. J. *Eur J Cancer* 15(2): 251-256; 1979.

Chromatography on benzoylated diethylaminoethylcellulose (BD cellulose) was used to study the damage and repair of rat kidney DNA following exposure of rats to renal carcinogens. Female Wistar rats were inoculated ip with dimethylnitrosamine (DMN: 0-40 mg/kg) or diethylnitrosamine (DEN: 0-200 mg/kg). DEN increased the fraction of renal DNA that bound to BD cellulose and subsequently eluted with 1.8% caffeine. The increase was proportional to DEN dose and was highest (59%) 24 hr after treatment. The amount of caffeine-eluted renal DNA was also approx proportional to DMN dose, and the amount eluted 4 hr after DMN administration was increased more than twofold in animals maintained on a glucose-sucrose diet. The max level of caffeine-eluted DNA was obtained 24 hr after treatment with 40 mg/kg DMN, and it was 140% greater than that in control animals. The level decreased slightly between 2 and 3 days after administration, and then it rose sharply at 4 days. After the fifth day, the level decreased again, and on day 7 it was approx 25% greater than the control level. The increase on day 4 may have been due to DMN-induced proliferative activity in the kidney. The replication of cells containing persistent carcinogen-induced damage may play an important role in this tumor induction system. (36 refs)

79-1966 Sequential Quantitative Studies on Hyperplastic Nodules in the Liver of Rats Treated with Carcinogenic Chemicals. (Eng) Tatematsu, M. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Murasaki, G.; Nakanishi, K.; Miyata, Y.; Shinohara, Y.; Ito, N. *Gann* 70(1): 125-130; 1979.

The induction of hyperplastic liver nodules in male Fischer

rats by a single dose of diethylnitrosamine (DEN, 200 mg/kg ip) followed 2 wk later by 10 wk of treatment with N-(2-fluorenyl)acetamide (2-FAA, 0.02% of the diet), the α -isomer of 1,2,3,4,5,6-hexachlorocyclohexane (α -BHC, 0.10% of the diet), or phenobarbital (PB, 0.05% of the diet) was studied. The animals were subjected to partial hepatectomy during the second week of carcinogen feeding. Treatment with DEN followed by 2-FAA, α -BHC, or PB resulted in the appearance of small foci on the surface of the liver within 4-8 wk. The cells in these nodules had a foamy, usually basophilic, cytoplasm and vesicular nuclei with prominent nucleoli. The av cross-sectional areas of the nodules increased during treatment. From week 6, significantly higher percentages of hyperplastic nodules per unit area of liver were found in all treated groups compared with the untreated controls. From week 8, significantly more nodules were found in the treated groups compared with the control group. Continuous administration of α -BHC or PB alone for 12 wk and partial hepatectomy did not induce hyperplastic nodules. Continuous administration of 2-FAA induced fewer nodules than did treatment with DEN followed by 2-FAA. (17 refs)

79-1967 Ultrastructure of Spontaneous Hepatic Neoplasms and of Neoplasms Induced by Diethylnitrosamine or Dieldrin in the C₃H Mouse (Meeting Abstract). (Eng) Ruebner, B. H. (Sch. Medicine, Univ. 79-1968 Cell Kinetics of Hepatocytes During the Preneoplastic Period of Diethylnitrosamine-induced Liver Carcinogenesis. (Eng) Rabes, H. M. (Inst. Pathology, Univ. Munich, Thalkirchnerstrasse 36, 8000 Munich 2, W. Germany); Szymkowiak, R. *Cancer Res* 39(4): 1298-1304; 1979.

Cell kinetic parameters of normal and preneoplastic enzyme-deficient hepatocytes were determined in male Wistar rats continuously fed diethylnitrosamine (DEN; 5mg/kg/day in drinking water). The fraction of labeled mitoses of all hepatocytes as a function of time after a single injection of ³H-thymidine revealed an increment in T-S from 9.6 to 11.6 hr at 20 and 118 days of DEN feeding, respectively. T-G₂ remained constant at 4 hr. The fraction of proliferating cells with a T-C < 40 hr increased from < 20% to 74% at 20 and 118 days, respectively. ATPase-deficient areas (islands) increased in cell number during the preneoplastic period, going from ≤ 25 cells/section at 30 days of feeding to ≤ 400 cells at 90 days and $\leq 5,000$ cells at 120 days. The labeling index after a single ³H-thymidine injection remained at 3%-4% until 90 days and then increased. The T-S's in enzyme-deficient (E-D) islands were 7.4 and 6.7 hr at 90 and 120 days, respectively. When the islands were evaluated as a function of size, a decrease of T-S was found in the larger E-D areas. E-D preneoplastic cells showed a proliferative advantage over nor-

mal liver cells. The E-D population responded to partial hepatectomy by an increase in DNA-synthesizing cells that was higher than that in the surrounding tissue. Partial hepatectomy shortened the preneoplastic period significantly when performed early after the start of DEN feeding. The proliferative advantage of a preneoplastic population may be explained in part by the increasing resistance of these cells against the toxic action of the carcinogen. (42 refs)

79-1969 Tumorigenicity of the Dihydrodiols of Dibenz(a,h)anthracene on Mouse Skin and in Newborn Mice. (Eng) Buening, M. K. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche, Inc., Nutley, NJ, 07110); Levin, W.; Wood, A. W.; Chang, R. L.; Yagi, H.; Karle, J. M.; Jerina, D. M.; Conney, A. H. *Cancer Res* 39(4): 1310-1314; 1979.

Dibenz(a,h)anthracene (DBA) and its three metabolically possible trans-dihydrodiols, trans-3,4-dihydroxy-3,4-dihydrobenz(a,h)anthracene (DBA 3,4-dihydrodiol), trans-1, 2-dihydroxy-1, 2-dihydrodibenz (a,h) anthracene (DBA 1,2-dihydrodiol), and trans-5,6-dihydroxy-5,6-dihydrodibenz(a,h)anthracene (DBA 5,6-dihydrodiol), were tested for tumorigenic activity on mouse skin and in newborn mice. A single topical application of 10-160 nanomoles (nmol) of the test compound to female CD-1 mice was followed 7 days later by application of 12-O-tetradecanoylphorbol-13-acetate (16 mol/200 μ g acetone, 2x/wk for 25 wk). DBA and DBA 3,4-dihydrodiol had the same tumorigenicity on mouse skin and were far more potent as skin tumor initiators than the 1,2- or 5,6-dihydrodiols. trans-3,4-Dihydroxy-1,2,3,4-tetrahydrodibenz(a,h)anthracene (DBA H₁-3,4-diol), which is saturated at position 1,2, was considerably less tumorigenic than DBA 3,4-dihydrodiol. Swiss-Webster BLU/Ha Icr strain mice were given 10, 20, and 40 nmol or 60, 120, and 240 nmol ip of the test compound on days 1, 8, and 15 of life (total doses 70 and 420 nmol respectively) and killed when 25-29 wk old. Less than 20% of control mice or mice treated with the 1,2- or 5,6-dihydrodiols developed pulmonary tumors. In mice treated with a total of 70 or 420 nmol of DBA, 88% and 100%, respectively, developed pulmonary tumors. In mice treated with 70 or 420 nmol of DBA 3,4-dihydrodiol, 83% and 99%, respectively, developed pulmonary tumors. Hepatic neoplastic nodules were found in 42% of the male mice treated with 420 nmol of DBA 3,4-dihydrodiol but not in female mice or in mice given any other treatment. These results support the prediction of the bay region theory that DBA 3,4-dihydrodiol is a proximate carcinogenic metabolite of DBA. (31 refs)

79-1973 Comparison of Mutagenicity, Antitumor Activity, and Chemical Properties of Selected Nitrosourea and Nitrosoamides. (Eng) Brundrett, R. B.

(Pharmacology Lab., Johns Hopkins Oncology Center, Baltimore, MD, 21205); Colvin, M.; White, E. H.; McKee, J.; Hartman, P. E.; Brown, D. L. *Cancer Res* 39(4): 1328-1333; 1979.

Several nitrosoureas and nitrosoamides were tested for mutagenicity in *Salmonella typhimurium*, in vitro cytotoxicity, in vivo toxicity, and antitumor activity against murine L1210 leukemia. In aqueous soln, N-(2-chloroethyl)-N-nitrosourea (CENU), N-nitroso-N-(2-chloroethyl)acetamide (CENA), N-methyl-N-nitrosourea (MNU), and N-methyl-N-nitrosoacetamide (MNA) decomposed by similar mechanisms (probably via diazohydroxide intermediate) to give analogous products. Of 10 compounds tested, only 3 nitrosoureas (MNU, CENU, and N,N'-bis(2-chloroethyl)-N-nitrosourea], showed a significant antitumor effect (> 20% increase in the life-span of treated animals). Although the compounds tested were toxic to the whole animal, the chloroethylnitrosoureas were significantly more toxic than the other compounds, except CENA. In the three cases in which pairs of analogs of equal chain length were tested for mutagenicity [MNA and MNU, CENA and CENU, and N-nitroso-N-(n-propyl)acetamide and N-nitroso-N-(n-propyl)urea] the nitrosourea was lower in mutagenic activity than the corresponding nitrosoamide. These findings indicate that in this series there is a dissociation of antitumor and mutagenic effects. The determination of the biochemical basis for this dissociation should lead to a better understanding of the chemical and biochemical determinants of antitumor effects vs mutagenicity (and, presumably, carcinogenicity). 79-1974 Characterization of Malignant Cell Populations in MNU-induced Leukaemia of Mice. (Eng)

Baines, P. (Paterson Lab., Withington, Manchester M20 9BX, England); Dexter, T. M.; Schofield, R. *Leuk Res* 3(1): 23-28; 1979.

The nature of methylnitrosourea (MNU)-susceptible target cells in intact and thymectomized (Th-x) BDF1 (C57BL/6 x DBA/2J F1) mice with MNU-induced (50 mg/kg iv) leukemias was studied. Th-x greatly prolonged the induction time and reduced the yield of MNU-induced leukemias. Leukemias of intact mice were commonly associated with thymic enlargement and with enlargement and leukemic infiltration of the spleen, lymph nodes, and liver. MNU-treated Th-x mice usually presented with enlarged mesenteric lymph nodes and/or enlarged spleens that were occasionally hemorrhagic. The leukemias of intact mice were more readily passaged to syngeneic recipients than those of Th-x mice. The leukemias in all cases were often comprised of undifferentiated blasts and lymphocytes. The enlarged, leukemic organs of the intact mice frequently contained large numbers of cells with Thy-1 + (T-cell) markers, whereas substantial proliferation of a Thy-1-, immunoglobulin-positive (Ig +) population was apparent in the affected organs of half of the Th-x mice. Half of the remaining leukemias in the Th-x animals were Ig + (B-cell) lymphomas and half showed low-intensity staining from both Thy-1 and Ig. Implants of neonatal thymus into syngeneic Th-x mice after MNU treatment did not reduce the induction time or increase the incidence of leukemias. Thymic lymphomas apparently developed only when the thymus had been directly exposed to MNU. Irradiation had no effect on MNU leukemogenesis. Leukemias of intact and Th-x mice do not appear to arise from a common target cell. In fact, MNU-induced thymic lymphoma arises from an intrathymic target population. (15 refs)

79-1975 Morphogenesis of Pancreatic Carcinoma in Organ-cultured Embryonic Rat Pancreas Induced by Methylnitrosourea (MNU) (Meeting Abstract). (Eng)

79-1976 Gastric Cancer Etiology: A Biochemical Hypothesis. (Eng) Lilienfeld, D. E.

(Dept. Epidemiology, Johns Hopkins Univ., Sch. Hygiene and Public Health, 615 N. Wolfe St., Baltimore, MD, 21205); Gargliano, C. F. *Med Hypotheses* 5(1): 145-151; 1979.

A two-stage biochemical model for the etiology of intestinal-type gastric cancer is proposed. The model postulates that the gastric mucosal barrier is biochemically pierced as a result of chemical interactions between the mucoproteins and mucopolysaccharides of the barrier and ingested polysaccharides (starches). This would allow the growth of gastric flora that could produce carcinogenic nitrosamines and/or nitrosamides. Evidence presented in favor of the model includes

the observation that a decline in starch consumption has preceded a decline in gastric cancer mortality in both the US and Japan. (35 refs)

79-1977 Effects of Dietary Administration of Cheno-deoxycholic Acid on Induced Colon Cancer in Rats (Meeting Abstract). (Eng) Sarwal, A. N. (New York Univ. Medical Center, Public Health Res. 79-1978 Effects of Phenobarbital (PB), Pregnenolone-16 α -carbonitrile (PCN) and 3-Methylcholanthrene (MC) on the Distribution of NADPH-Cytochrome c (Cytochrome P-450) Reductase in Rat Liver (Meeting Abstract). (Eng) Taira, Y. (Dept. Pharmacology, Univ. Iowa, Iowa City, IA, 52242); Greenspan, P.; Kapke, G.; Redick, J.; Baron, J. *Fed Proc* 38(3, part 1): 691; 1979. (no refs)

79-1979 Effects of Phenobarbital and 3-Methylcholanthrene on the Distributions of Cytochromes P-450 in Rat Liver (Meeting Abstract). (Eng) Baron, J. (Dept. Pharmacology, Univ. Iowa, Iowa City, IA, 52242); Redick, J. A.; Kapke, G. F.; Guengerich, F. P. *Fed Proc* 38(3, part 1): 660; 1979. (1 ref)

79-1980 Immunological Comparison of Hepatic and Extrahepatic Cytochromes P-450. (Eng) Guengerich, F. P. (Dept. Biochemistry, Vanderbilt Univ. Sch. Medicine, Nashville, TN, 37232); Mason, P. S. *Mol Pharmacol* 15(1): 154-164; 1979.

Antibodies to two apparently homogenous cytochromes P-450 prepared from the liver microsomes of phenobarbital (PB) and 3-methylcholanthrene (3-MC)-treated male Sprague-Dawley rats were used to examine the similarity between hepatic and extrahepatic P-450's from PB- and 3-MC-treated rats. At least one microsomal preparation from liver, lung, kidney, testis, spleen, heart, small intestine, colon, stomach, and brain showed a visible reaction with one of the liver P-450 antibodies in double-diffusion analyses. The benzo(a)pyrene hydroxylase or 7-ethoxycoumarin O-deethylase activity of microsomes from each tissue except spleen and colon was inhibited by the liver P-450 antibodies, the degree of inhibition being dependent on the substrate, antibody, and drug treatment of the rats from which the microsomes were prepared. In general, microsomes from 3-MC-treated rats were inhibited most readily by antibody to cytochrome P-450 isolated from the liver microsomes of 3-MC-treated rats; the same was true for PB induction, although many exceptions were noted. The results indicate that hepatic and extrahepatic

P-450's are, in general, similar as judged by immunological techniques. (36 refs)

79-1981 Dose-dependent Fate of 1,4-Dioxane in Rats. (Eng) Young, J. D. (Toxicology Res. Lab., Dow Chemical Co., 1803 Building, Midland, MI, 48640); Braun, W. H.; Gehring, P. J. *J Toxicol Environ Health* 4(5/6): 709-726; 1978.

A pharmacokinetic study showed that the fate of 1,4-dioxane in rats is markedly dose-dependent because of their limited capacity to metabolize dioxane to β -hydroxyethoxyacetic acid. Correlation of the dose-dependent fate of dioxane with the results of toxicological studies in rats supported the conclusion that there is an apparent threshold for the toxic effects of dioxane that coincides with saturation of the metabolic pathway for its detoxification. (28 refs)

79-1982 Results of a Two-Year Chronic Toxicity and Oncogenicity Study of 2,3,7,8-Tetrachlorodibenzo-p-dioxin in Rats. (Eng) Kociba, R. J. (Toxicology Res. Lab., Health and Environmental Res., Dow Chemical U.S.A., Midland, MI, 48640); Keyes, D. G.; Beyer, J. E.; Carreon, R. M.; Wade, C. E.; Dittenber, D. A.; Kalnins, R. P.; Frauson, L. E.; Park, C. N.; Barnard, S. D.; Hummel, R. A.; Humiston, C. G. *Toxicol Appl Pharmacol* 46(2): 279-303; 1978.

Groups of Sprague-Dawley rats were maintained for up to 2 yr on diets supplying 0.1 μ g [2,193 parts per trillion (ppt)], 0.01 μ g (208 ppt), or 0.001 μ g (22 ppt) of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD)/kg/day. A dose of 0.1 μ g/kg/day increased the incidence of hepatocellular carcinomas (female only) and squamous cell carcinomas of the lung, hard palate/nasal turbinates, and tongue, but it decreased the incidence of tumors of the pituitary, uterus, mammary gland, pancreas, and adrenal gland compared with controls. Morphological changes in hepatic, lymphoid, respiratory, and vascular tissue were seen by light and electron microscopy. The primary hepatic ultrastructural changes at this high dose level was proliferation of the rough endoplasmic reticulum. Other toxic effects included increased mortality, decreased wt gain, increased urinary excretion of porphyrins and δ -aminolevulinic acid, slight depression of erythroid parameters, and increased serum activities of alkaline phosphatase, γ -glutamyl transferase, and glutamic-pyruvic transaminase. Rats treated with 0.01 μ g/kg/day generally showed a lesser degree of toxicity, and treatment with the lowest dose caused no effects of toxicologic importance. Liver and fat samples collected at terminal necropsy (after 2 yr of treatment) of rats of the three dosage groups contained 24,000 and 8,100, 5,100 and 1,700, and 540 and 540 ppt of TCDD, respectively. It is concluded that doses sufficient to induce severe toxicity increased the incidence of some types of neoplasms in rats and reduced the incidence

of others. There was no increase in neoplasms in rats receiving TCDD doses that induced slight or no manifestations of toxicity. (9 refs)

79-1983 Different Effect of 2,3,7,8-Tetrachlorodibenzo-p-dioxin on Glucuronide Conjugation of Various Aglycones. Studies in Wistar and Gunn Rats. (Eng) Aitio, A. (Dept. Physiology, Univ. Turku, Kiinamyllynkatu 10, SF-20520 Turku 52, Finland); Parkki, M. G.; Marniemi, J. *Toxicol Appl Pharmacol* 47(1): 55-60; 1979.

The effect of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD: 20 µg/kg intragastrically) on the activity of uridine diphosphate-glucuronosyltransferase (UDPGT) in the liver and kidney was studied in adult Gunn (G), Wistar (W), and W-G hybrid rats. In the W rats, TCDD caused an 8-fold increase in liver UDPGT activity toward 4-methylumbelliferone (4-MU), a 2-fold increase in kidney UDPGT toward 4-MU, an 8-fold increase in the liver conjugation of o-aminophenol (o-AP), and p-nitrophenol (p-NP), a 2-fold increase in the renal conjugation of o-AP and p-NP, and no effect on the hepatic or renal conjugation of bilirubin. In the W-G hybrids, TCDD caused a 5-fold increase in the liver conjugation of 4-MU, a 2-fold increase in the kidney conjugation of 4-MU, a 7-fold increase in the liver conjugation of o-AP and p-NP, and a 2-fold increase in the kidney conjugation of o-AP and p-NP; there was no effect on the activity of UDPGT toward bilirubin. TCDD had no effect on the hepatic or renal conjugation of any aglycone in the Gunn rats. Diethylnitrosamine (15 mM in the in vitro incubation mixture) had no effect on the conjugation of 4-MU, nonsignificantly decreased the conjugation of bilirubin, markedly increased the hepatic activity of UDPGT in untreated (especially G) rats, and had no effect on the hepatic or renal conjugation of o-AP or p-NP in the TCDD-treated rats. (24 refs)

79-1984 Comparison of Phenobarbital- and Carcinogen-induced Aldehyde Dehydrogenases in the Rat. (Eng) Marselos, M. (Dept. Physiology, Univ. Kuopio, Kuopio 10, Finland); Torronen, R.; Koivula, T.; Koivusalo, M. *Biochim Biophys Acta* 583(1): 110-118; 1979.

The induction of liver aldehyde dehydrogenase (AD) activity by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD, 80 µg/kg, ip), phenobarbital (PB, 1 mg/ml in the drinking water for 7 days), 2-acetamidofluorene (AAF, 0.02% of the diet for 3 mo), and various carcinogenic agents was studied in Sprague-Dawley (chronic AAF treatment only) and Wistar/AF/Han/Mol/(Han 67) rats. Substrain rr of the latter strain showed no induction of liver or intestinal postmitochondrial fraction AD activity after PB, whereas both activities were increased (7- and 2-fold, respectively) in substrain RR rats. TCDD caused a 40-fold increase in liver AD and a significant increase in serum AD in both strains. Acute administration of AAF or urethan (100

mg/kg intragastrically for 4 days) had no effect on the liver or small intestinal AD of rr rats, whereas a 40-fold increase was seen after 3-methylcholanthrene (100 mg/kg), a 30-fold increase after benzo(a)pyrene (100 mg/kg), and a 2-fold increase after chrysene (200 mg/kg). The latter three compounds were also given intragastrically for 4 days. Chronic AAF administration resulted in a 15-fold increase in liver AD. The activities induced by TCDD and the carcinogenes showed similar isoelectric focusing patterns in gel slabs and similar mol wts, as determined by gel chromatography. These activities were clearly differentiated from the normal cytoplasmic activity and from that induced by PB. (19 refs)

79-1985 Inhibitory and Mutagenic Effects of Sodium Nitroprusside and Its Adenine Complex on *Escherichia coli*. (Eng) Szilagyi, I. (Inst. Biology, Univ. Medical Sch., P.O. Box 23, H-4012 Debrecen, Hungary); Vitalis, S. *Acta Microbiol Acad Sci Hung* 25(4): 285-289; 1978.

Sodium nitroprusside and its adenine complex decreased the growth rate of exponentially growing *Escherichia coli* cultures, and the adenine complex was actually bactericidal. The adenine complex failed to induce base-pair substitutions in *E. coli* in mutagenicity experiments; however, these experiments did not exclude the possibility of weak mutagenicity or the induction of frameshift mutations. (5 refs)

79-1987 Comparative Carcinogenicity of Vinyl or Imine Bridged 5-Nitrofurans in the Rat (Meeting Abstract). (Eng) Erturk, E. (Dept. Human Oncology, Univ. Wisconsin Center Health Sciences, Madison, WI, 53792); Headley, D. B.; Bryan, G. T. *Fed Proc* 38(3, part 2): 1403; 1979. (no refs)

79-1988 Azide Mutagenesis in Gram-negative Bacteria. Reversion of the Mutagenic Effect by L-Cysteine. (Eng) Ciesla, Z. (Inst. Biochemistry and Biophysics, Polish Acad. Sciences, ul. Rakowiecka 36, 02-532 Warsaw, Poland); Filutowicz, M. *Mutat Res* 66(3): 301-305; 1979.

Several experiments were conducted to determine the mechanism of the mutagenic action of azide (AZ). Prior inhibition of DNA synthesis with nalidixic acid (10 µg/ml) did not significantly alter the mutagenicity of AZ (3 mM) in *Sal-*

monella typhimurium strain TA1530, which suggests that DNA replication is not required for AZ mutagenicity. In a search for the metabolic pathway that may be involved in the activation of AZ to the ultimate mutagen (UM), the effect of L-cystine or L-cysteine (each, 0.5 mM) on the mutagenicity of 0.02 mM AZ in strain 1530 was determined. Both amino acids reduced the number of mutations to near control levels. This effect was specific, as other compounds containing the SH group (cysteamine and mercaptoethanol) did not affect the mutation rates. The possibility that AZ may be a substrate to one of the L-cysteine biosynthetic enzymes and that repression of the enzyme by L-cystine would result in a decreased rate of AZ metabolism (and, thus, UM concentration) was also tested. The mutagenicity of AZ in *S. typhimurium* strain TK1825 (which carries the *cysB1532* mutation plus *uvrB* and *hisG46*) was reduced significantly by L-cystine. The mutagenicity of AZ was much lower in TK1825 than in TA1530, an expected result if the cellular concentration of L-cysteine in TK1825 is higher than that in wild-type bacteria. The results do not necessarily mean that AZ is not metabolized by L-cystine enzymes that are repressed by growth in the presence of L-cystine. Two other possible explanations of the effect of L-cystine on AZ mutagenesis are given: cysteine desulfhydrase could be involved in inactivation of the UM, or L-cysteine and L-cystine may react with the UM. (18 refs)

- 79-1989 **Morphologic Response of Cultured Rat Pancreatic Ducts to Carcinogens (Meeting Abstract).** (Eng) Holmquist, D. R. (Dept. Biological Sciences, Univ. New Orleans, New Orleans, LA, 70122); Whelan, J. F.; Githens, S.; Ruby, J. R. *Lab Invest* 40(2): 260-261; 1979. (no refs)

- 79-1990 **The Dietary Administration of L-Monosodium Glutamate, DL-Monosodium Glutamate and L-Glutamic Acid to Rats.** (Eng) Ebert, A. G. (International Glutamate Technical Committee, P.O. Box 744, Westwood, MA, 02090). *Toxicol Lett* 3(2): 71-78; 1979.

The effects of dietary L-monosodium glutamate, DL-monosodium glutamate, and L-glutamic acid (0.1% or 0.4% of the diet for up to 2 yr beginning at 12 wk of age) were studied in Sprague-Dawley rats. None of the treatments affected body wt gain, food intake, general behavior, hematologic parameters, organ wt, or fertility. Combined survival to 730 days was 57.3% for the treated rats and 59.3% for controls. Tumor incidence was 40.1% in the treated animals and 42.4% in the controls. Most tumors in females were mammary adenomas and most in males were benign tumors of dermal origin. The findings are essentially in agreement with others published in the literature. (11 refs)

- 79-1991 **The Dietary Administration of Monosodium Glutamate or Glutamic Acid to C-57 Black Mice for Two Years.** (Eng) Ebert, A. G. (International Glutamate Technical Committee, P.O. Box 744, Westwood, MA, 02090). *Toxicol Lett* 3(2): 65-70; 1979.

The effects of dietary L-monosodium glutamate, DL-monosodium glutamate (DL-MSG), and L-glutamic acid (1.0% or 4.0% of the diet for 715 days) on tumorigenesis were studied in male C57 black mice. There was no consistent relationship between treatment and mortality. Hematologic findings at 280 days did not differ between control and treated mice. Histopathologic examination of gross lesions detected at postmortem and of routine visceral tissue samples revealed only a single neoplasm--a benign lung adenoma in a mouse given 1% DL-MSG. The other histologic changes were indicative of age or chronic inflammatory processes and did not differ between control and treated mice groups. Thus, no evidence of carcinogenic potential was found for any of the substances tested. (5 refs)

- 79-1992 **Promoting Effect of Saccharin and DL-Tryptophan in Urinary Bladder Carcinogenesis.** (Eng) Cohen, S. M. (Dept. Pathology, St. Vincent Hosp., Worcester, MA, 01504); Arai, M.; Jacobs, J. B.; Friedell, G. H. *Cancer Res* 39(4): 1207-1217; 1979.

The existence of at least two stages in bladder carcinogenesis was investigated in male Fischer rats using N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT: 0.2% of diet for 6 wk; av cumulative dose 1.5 g) as the initiator. Sodium saccharin (SS) and DL-tryptophan (TP) were fed at 5% and 0.2% of the diet, respectively, starting either immediately after or 6 wk after FANFT administration. After 2 yr, rats fed the control diet (42 rats), SS (20), or TP (20) had no urinary bladder lesions. The group fed FANFT followed by control diet developed one papilloma and four bladder carcinomas. All rats fed FANFT for 36 wk or for their lifetime (78 rats) had bladder carcinomas, and several had invasive lesions. Rats fed FANFT + SS or TP, either immediately after FANFT feeding or after FANFT + 6 wk of control diet, developed high incidences of bladder cancer. SS was a much more potent promoting agent than TP, inducing higher incidences of bladder tumors with a shorter latent period and producing tumors that were more invasive. Sequential epithelial changes were observed by scanning and transmission electron microscopy as well as by light microscopy. Pleomorphic microvilli were present on the superficial cells of all tumors examined and on the surface cells of hyperplastic bladder epithelium after 6 wk of FANFT + 6 wk of SS, but not after 6 wk of FANFT + 6 wk of control diet or 6 wk of TP. These results are consistent with the two stage theory of urinary bladder carcinogenesis and suggest that SS and TP might act as tumor-promoting agents. (68 refs)

79-1995 Chemical Carcinogens Produce Mutations to Ouabain Resistance in Transformable C3H/10T1/2 Cl 8 Mouse Fibroblasts. (Eng) Landolph, J. R. (Los Angeles County-Univ. Southern California Comprehensive Cancer Center., Los Angeles, CA, 90033); Heidelberger, C. *Proc Natl Acad Sci USA* 76(2): 930-934; 1979.

A mutation assay for ouabain-resistant mutants in the transformable C3H/10T1/2 Cl 8 mouse fibroblast cell line, in which there is a correspondence between morphologic and malignant transformation, is described. Chemical carcinogens induce mutations to ouabain resistance in C3H/10T1/2 Cl 8 cells. The mutant phenotype is stable and heritable in the absence of a selective agent, and dose-response curves for mutation frequency were obtained with N-methyl-N'-nitro-N-nitrosoguanidine, 3-methylcholanthrene, benzo(a)pyrene (BP), N-acetoxy-N-2-acetylaminofluorene and anti-7,8-diol-9,10-epoxide of BP. The ratio of the malignant transformation frequency to the mutation frequency was 12 for BP and 21 for N-acetoxy-N-2-acetylaminofluorene. With this mutation assay the C3H/10T1/2 Cl 8 cell line can be used to compare mutation and transformation frequencies to screen for xenobiotics that pose mutagenic or carcinogenic hazards to mammalian cells. 79-1996 Fatty Acids, Oral Contraceptive and Aflatoxin Interrelationships (Meeting Abstract). (Eng) Rogel, A. (Sch. Public Health, Univ. California Los Angeles, Los Angeles, CA, 90024); Aftergood, L.; Alfin-Slater, R. B. *Fed Proc* 38(3, part 1): 713; 1979. (no refs)

79-1997 Mutagenicities of 4-Hydroxy-1,4-benzoxazinones Naturally Occurring in Maize Plants and of Related Compounds. (Eng) Hashimoto, Y. (Faculty Pharmaceutical Science, Univ. Tokyo, 7-3-1, Hongo, Bunkyo-ku, Tokyo 113, Japan); Shudo, K.; Okamoto, T.; Nagao, M.; Takahashi, Y.; Sugimura, T. *Mutat Res* 66(2): 191-194; 1979.

The mutagenicity of two naturally occurring 4-hydroxyben-

zoxazinones and eight synthetic analogs was assayed in the *Salmonella typhimurium*/rat liver microsome system. 2,4-Dihydroxy-1,4-benzoxazinone and 2,4-dihydroxy-7-methoxy-1,4-benzoxazinone, which occur naturally in such cereal plants as maize, wheat, and rye, and 4-hydroxy-7-methoxybenzoxazinone and 4-hydroxy-6-methoxybenzoxazinone were mutagenic in *Salmonella* strains TA100 and TA98. The presence of the 2-hydroxy group or the 7-methoxy group seems to be required for mutagenic activity. The two naturally occurring compounds have sufficiently high specific mutagenicities to be regarded as naturally occurring mutagens and further studies are required on their distribution in plants and animal foods. 79-1998 Effects of Some Carcinogens on Conformation of Histones. (Eng) Su, Y. Y. (Neurosensory Center, Baylor Coll. Medicine, Houston, TX, 77030); Jirgensons, B. *Makromol Chem* 180(2): 367-373; 1979.

The effects of 4-nitroquinoline N-oxide (4-NQO), 13-H-dibenzo(c,j)carbazole (13-HDBC), and 7-H-dibenzo(c,g)carbazole (7-HDBC) on the conformation of histones F1 (H1), F2a (H2A), F2b (H2B), and F3 (H3) were studied using a circular dichroism (CD) probe. 4-NQO had no effect on the tertiary structure of F1, whereas the two carbazoles modified it slightly. The main chain conformation of F1 was not affected by any of the carcinogens. The tertiary structure of F2a was affected by all three carcinogens, with the strongest enhancement of the CD bands assigned to tyrosine and phenylalanine chromophores being produced by 7-HDBC. 4-NQO had a very weak effect on the main chain conformation of F2a, but the two carbazoles promoted helix formation of this histone. The effects of the carcinogens on F2b were similar to those on F2a but not as pronounced. 7-HDBC produced extrinsic Cotton effects in the 300- to 380-nanometer (nm) spectral zone of F2a and F2b. The main chain conformation of F3 was not significantly affected by the carcinogens. However, both carbazoles enhanced the bands related to the tyrosine and phenylalanine chromophores and produced extrinsic Cotton effects in the 300- to 380-nm spectral zone. The results show that the three carcinogens interacted with some of the histone fractions, thereby altering the conformation of the histones. (20 refs)

79-1999 Further Characterization of Atypical Acinar Cell Nodules (AACN) of the Pancreas in Carcinogen Treated Rats (Meeting Abstract). (Eng) Shinozuka, H. (Dept. Pathology, Univ. Pittsburgh, Pittsburgh, PA, 15261); Katyal, S. L. *Fed Proc* 38(3, part 2): 1403; 1979. (no refs)

79-2000 Histochemical Differences Between So-Called

79-2000 Megalocytosis and Neoplastic or Preneoplastic Liver Lesions Induced by N-Nitrosomorpholine. (Eng) Taper, H. S. (Dept. General Pathology and Neuropathology, Univ. Louvain, avenue E. Mounier, 52 (ANPG 52.60), B-1200 Bruxelles, Belgium); Bannasch, P. *Eur J Cancer* 15(2): 189-196; 1979.

The histochemistry of the so-called megalocytes and preneoplastic or neoplastic hepatocytes was studied in the livers of male Sprague-Dawley rats treated with N-nitrosomorpholine (NNM: max of 20 ml/day of a 50% aqueous soln as drinking water for 3 wk). Immediately after NNM treatment, the lobular architecture of the liver parenchyma was greatly altered by hepatocellular necrosis, a pronounced loss of the parenchyma, and an intense reactive proliferation of bile ducts or mesenchymal cells. The megalocytes, which are very numerous, had a cytoplasm poor in glycogen and rich in pyroninophilic material. Nuclease activity was normal or increased. The clear and acidophilic hepatocytes, which are considered to be preneoplastic, showed excessive storage of glycogen and usually had decreased or absent nuclease activity. Most of the megalocytes disappeared within 3 wk after withdrawal of the carcinogen, whereas the clear and acidophilic cells persisted for up to 50 wk. The latter cells were found in the numerous foci and rare neoplastic nodules containing altered liver cells. Fifty weeks after withdrawal of NNM, three of four rats had hepatocellular carcinomas. The cells of these tumors showed distinct basophilia, a complete absence of glycogen, and an almost complete absence of nuclease activity. The megalocytes appeared to result from an interaction between toxic and regenerative events. (19 refs)

79-2001 Conversion of 2,4,6-Trinitrophenol to a Mutagen by *Pseudomonas aeruginosa*. (Eng) Wyman, J. F. (Naval Biosciences Lab., Sch. Public Health, Univ. California, Berkeley, CA, 94720); Guard, H. E.; Won, W. D.; Quay, J. H. *Appl Environ Microbiol* 37(2): 222-226; 1979.

The biodegradation of 2,4,6-trinitrophenol (picric acid) by *Pseudomonas aeruginosa* and its mutagenicity for *Salmonella typhimurium* were studied. Anaerobic incubation of *P. aeruginosa* with picric acid resulted in a 2-log increase in cell number during the first 24 hr, followed by a relative stability in bacterial counts (10^5 - 10^7 cells/ml) for 30 days. Reduction of picric acid to 2-amino-4,6-dinitrophenol (picramic acid) by the bacteria was shown by a change in the color of the medium from yellow to reddish brown. Thin-layer chromatography, nuclear magnetic resonance, and UV spectrometry identified two of the three substances present as picric and picramic acids; the third degradation product was not identified. The picric acid concentration in the medium decreased approx 22% during the 30 days of incubation, with approx 1.7% of the concentration that was lost being converted to picramic acid. Picric acid (10 µg/plate) was mutagenic to *S. typhimurium* (frameshift and base-substitution mutations) only after activation with a rat liver homogenate preparation. Picramic acid proved to be a potent base-substitution muta-

gen and a somewhat weaker frameshift mutagen without activation by the rat liver preparation. (16 refs)

79-2003 Carcinogenicity and Chronic Toxicity of 2,4-Toluenediamine in F344 Rats. (Eng) Cardy, R. H. (Dept. Pathology, Litton Bionetics, 5516 Nicholson Lane, Kensington, MD, 20795). *J Natl Cancer Inst* 62(4): 1107-1116; 1979.

The aromatic amine 2,4-toluenediamine, which is used in the manufacture of polyurethane foams, was fed at levels of 50 and 100 ppm to inbred, barrier-raised F344 rats for 2 yr. The high dose induced a statistically significant increase in the incidence of hepatic neoplasia in males, and it induced a significant dose-related positive trend in the incidence of liver neoplasms in both sexes. Hepatocellular changes (foci and larger areas of clear cell-type cellular alteration and a few basophilic foci) considered to be associated with neoplasia were increased at a high level of statistical significance in both sexes. In addition, the compound caused statistically significant increases in the incidence of mammary tumors in females and an increase of mammary tumors in males that, although not significant statistically, was nevertheless considered to be related to the chemical. The compound was hepatotoxic and it accelerated the development of chronic renal disease in this strain, an effect that contributed to a marked decrease in the survival of dosed animals. (8 refs)

79-2004 The Decreased Degradation of Various Cell Constituents During Azodye-induced Carcinogenesis (Meeting Abstract). (Eng) Fiala, S. (Veterans Admin. Medical Center, Martinsburg, WV, 25401); Kettering, W. G. *Fed Proc* 38(3, part 2): 1403; 1979. (1 ref)

79-2005 Analgesic Nephropathy and Urinary-Tract Carcinoma. (Eng) Gonwa, T. A. (Bowman Gray Sch. Medicine, Wake Forest Univ., Winston-Salem, NC); Buckalew, V. M.; Corbett, W. T. *Ann Intern Med* 90(3): 432-433; 1979.

Epidemiologic studies implicating analgesic abuse in the development of urinary tract carcinomas are reviewed, and a case report illustrating the typical features of urinary tract cancer in analgesic abusers is presented. Approx 130 cases of urinary tract carcinomas related to analgesic abuse have

been reported worldwide. In all cases, phenacetin (PA) was the suspected carcinogen. When rats were fed PA for up to 110 wk, they developed a high degree of urothelial hyperplasia with some dysplasia. Metabolites of PA that were isolated from rats fed PA were carcinogenic in rats. The case report is that of a 37-yr-old woman with a history of sterile pyuria and chronic headache. Bilateral renal papillary necrosis was discovered following the onset of hematuria. A transitional cell carcinoma of the bladder and ureter was removed 2 yr later, but the patient died of metastatic disease 1 yr following surgery. She had consumed four to six headache powders (each containing 325 mg PA) daily for at least 20 yr before her death. (10 refs)

- 79-2006 Tumors on Sprague-Dawley Rats Induced by Long-Term Feeding of Phenacetin.** (Eng) Isaka, H. (Dept. Pathology, Kagoshima Univ. Sch. Medicine, 1208-1 Usuki-cho, Kagoshima 890, Japan); Yoshii, H.; Otsuji, A.; Koike, K.; Nagai, Y.; Koura, M.; Sugiyasu, K.; Kanabayashi, T. *Gann* 70(1): 29-36; 1979.

The carcinogenicity of phenacetin (PA) was studied in male and female Sprague-Dawley rats, who were fed a 2.5% or 1.25% PA diet for 18 mo and then a basal diet for 6 mo. The mortality rats in the PA-treated animals was 65%, compared with 20%-40% in control rats fed only the basal diet. Tumors developed in 26/27 males and 21/27 females given 2.5% PA, 20/22 males and 19/25 females given 1.25% PA, and 1/19 males and 6/25 females in the control group. Tumors first appeared in the 2.5% PA group at 47 wk and in the 1.25% PA group at 60 wk. The target organs of PA carcinogenesis were the nasal cavity (adenocarcinoma, squamous cell carcinoma, and transitional cell carcinoma) and urinary tract (renal cell carcinoma, transitional cell carcinoma). In the control group, tumors appeared in the lung, mammary gland, uterus, large intestine, and pituitary gland. The control tumors were regarded as strain-specific spontaneous tumors of Sprague-Dawley rats; they occurred more frequently in the PA-treated rats than in the controls. The results indicate that PA is carcinogenic in rats. (19 refs)

- 79-2007 Separation and Characterization of Highly Purified Forms of Liver Microsomal Cytochrome P-450 from Rats Treated with Polychlorinated Biphenyls, Phenobarbital, and 3-Methylcholanthrene.** (Eng) Ryan, D. E. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche Inc., Nutley, NJ, 07110); Thomas, P. E.; Korzeniowski, D.; Levin, W. *J Biol Chem* 254(4): 1365-1374; 1979.

The chromatographic separation of three highly purified forms of cytochrome (CC) P-450 (P-450a, P-450b, and P-450c), isolated from the hepatic microsomes of rats treated with the polychlorinated biphenyl mixture Aroclor 1254 is described. Each form showed a single protein-staining band

on sodium dodecyl sulfate-polyacrylamide gels with a minimum mol wt of 48,000 (P-450a), 52,000 (P-450b), and 56,000 (P-450c). CC's P-450a and P-450b were obtained from phenobarbital (PB)-treated rats, and CC's P-450a and P-450c were isolated from 3-methylcholanthrene (3-MC)-treated rats. CC P-450b was the major hemeprotein inducible by PB, and CC P-450c was the predominant hemeprotein induced by 3-MC. The CO-reduced difference spectral peak of CC P-450a was at 452 nanometers (nm), that of P-450b at 450 nm, and that of P-450c was at 447 nm. CC P-450a preferentially hydroxylated testosterone at the 7 α position but has low catalytic activity for the metabolism of benzphetamine, benzo(a)pyrene, 7-ethoxycoumarin, and zoxazolamine. CC P-450b catalyzes the hydroxylation of testosterone at the 16 β position and the demethylation of benzphetamine most efficiently. CC P-450c had very high catalytic activity for benzo(a)pyrene and zoxazolamine hydroxylation and 7-ethoxycoumarin O-dealkylation. Aniline was hydroxylated by the three forms of CC P-450 at comparable rates. Antisera prepared against CC's P-450a, P-450b, or P-450c did not cross-react with the heterologous antigens in Ouchterlony double-diffusion plates. When CC's P-450a, P-450b, and P-450c were subjected to limited proteolysis in the presence of sodium dodecyl sulfate, the resulting peptide maps provided additional evidence that these hemeproteins are structurally distinct. The forms of CC P-450 obtained from PB- and 3-MC-treated rats were indistinguishable from the corresponding forms from Aroclor 1254-treated rats by all criteria examined. (61 refs)

- 79-2008 Induction of Hepatic Mixed Function Oxidases in Senescent Rodents-II. Effect of Polychlorinated Biphenyls.** (Eng) Birnbaum, L. S. (Masonic Medical Lab., Utica, NY, 13503); Baird, M. B. *Exp Gerontol* 13(6): 469-477; 1978.

The effect of polychlorinated biphenyls (PCB's: 500 mg/kg Aroclor 1254 ip 5 days before sacrifice) on the age-related decline in coordinated hepatic monooxygenase activities was studied in male CFN rats. Hepatic microsomal levels of cytochrome P-450, NADPH cytochrome c reductase, and total lipid (mg lipid/mg microsomal protein) and the ability to respond to an inductive challenge of PCB's did not change significantly with age. Levels of NADPH cytochrome P-450 reductase, phospholipid [(PL): μ g PL phosphate/mg microsomal protein], and PL lipid (μ g PL phosphate/mg lipid) decreased with age, but the decreases were all at least partially reversed by treatment with PCB. The age-related difference in the metabolism of ethylmorphine and benzphetamine was also obliterated by PCB, and benzo(a)pyrene hydroxylase activity was affected by PCB to a greater extent in old rats than in young rats. Multiple cytochrome P-450 peptides were present in the region between 45,000 and 60,000 daltons on polyacrylamide gel slabs, but of four peptides present in both untreated and PCB-treated rats, only the 52,000-dalton species may represent a cytochrome P-450 molecule common to both. Electrophoretic profiles were the same for young,

middle-aged, and old rats. The results indicate that old rats exhibit no age-related impairment in their capacity to respond to inducers of hepatic drug metabolism. (47 refs)

- 79-2009 Reduction of 4-(5-Nitro-2-furyl)thiazole by Rat Liver Subcellular Fractions (Meeting Abstract).** (Eng) Swaminathan, S. (Dept. Human Oncology, Univ. Wisconsin Center for Health Sciences, Madison, WI, 53792); Lower, G. M.; Bryan, G. T. *Fed Proc* 38(3, part 1): 369; 1979. (no refs)

- 79-2010 Mutagenicity of the Non-carcinogenic Dibenzylnitrosamine and an Alpha-Acetoxy Derivative.** (Eng) Jacobson, M. K. (Dept. Chemistry, North Texas State Univ. at Denton, Denton, TX, 76203); Barton, R. A.; Yoder, S. S.; Sigh, S.; Lyle, R. E. *Cancer Lett* 6(2): 83-87; 1979.

The mutagenicity of a noncarcinogenic nitrosamine, N,N-dibenzylnitrosamine, and a chemically synthesized α -acetoxy derivative, N-(α -acetoxybenzyl)-N-benzylnitrosamine, was assayed in *Salmonella typhimurium* TA100 and TA1535. N,N-dibenzylnitrosamine was not mutagenic at doses up to 2 micromoles when tested directly or in the presence of a metabolic activation system; higher doses were toxic to the tester strains. The α -acetoxy derivative, however, was mutagenic both with and without metabolic activation. In contrast to previous reports with another α -acetoxy nitrosamine derivative, the mutagenic response was greatly reduced in the presence of the activating system. The differences in mutagenicity between the two compounds may be due to stereochemical and/or conformational differences that affect hydrolysis rates of the acetoxy group. (13 refs)

- 79-2011 Lidocaine Uptake and DL-Propranolol Effect on Isolated Hepatocytes (Meeting Abstract).** (Eng) Chen, C. P. (Sch. Pharmacy, Univ. Connecticut, Storrs, CT, 06268); Vu, V. T.; Cohen, S. D. *Fed Proc* 38(3, part 1): 700; 1979. (no refs)

- 79-2012 Drug Metabolizing Enzymes During Feeding of the Carcinogen 2-Aminoanthraquinone (Meeting Abstract).** (Eng) Ramanathan, R. (NIH, Bethesda, MD, 20014); Reddy, T. V.; Weisburger, E. K. *Fed Proc* 38(3, part 1): 661; 1979. (no refs)

- 79-2013 Clofibrate and Malignancy (Letter to Editor).** (Eng) MacGregor, G. A. (St. Luke's Hosp., Guildford, Surrey GU1 3NT, England). *Lancet* 1(8113): 445; 1979.

The case of a 50-yr-old man who died from jejunal adenocarcinoma following 15 yr of treatment with clofibrate is presented. The patient had also taken cholestyramine intermittently for 8 yr. (5 refs)

- 79-2014 Absence of Noxious Effects of Selected Neuroleptics in Dominant-Lethal Mutagenesis Assay.** (Eng) Sykora, I. (Res. Inst. Pharmacy and Biochemistry in Prague, Branch Inst., Pardubice-Rosice, Czechoslovakia); Gandalovicova, D.; Rezabek, K. *Mutat Res* 66(3): 291-299; 1979.

No dominant-lethal effect was induced in mice by the neuroleptics prothiaden, imipramine, oxyprothepin decanoate, or docloxythepin, even when administered at doses several times greater than the clinical doses. (15 refs)

- 79-2015 Polycyclic Compounds. XII. Vicinal cis/trans-Isomeric Dihydrodiols in the Hexahydrophenanthrene and Hexahydrobenz(a)anthracene Series.** (Ger) Malchow, A. (Institut für Organische Chemie, Technischen Hochschule Darmstadt, Olshausenstrasse 40-60, D-2300 Kiel, W. Germany); Kirrstetter, R. G.; Tochtermann, W. *Chem Ber* 112(2): 532-540; 1979.

The syntheses of the vicinal trans-dihydrodiols trans-9,10-dihydroxy-9-methyl-3,4,9,10-tetrahydrophenanthrene-1(2H)-one and trans-5,6-dihydroxy-6-methyl-2,3,5,6-tetrahydrobenz[a]anthracene-4(1H)-one and their cis-isomers are described. The chemistry and biochemistry of compounds of this type are of interest because of their potential carcinogenicity and mutagenicity. (18 refs)

- 79-2016 Inhibition of the Development of the Mammary Glands of Mice with a Bromotriphenylethylene.** (Eng) Rendon, A. M. (Equipe de Recherches 190 du CNRS, Fondation Curie, 26, rue d'Ulm, 75005 Paris, France); Rudali, G.; Guggiari, M. *Biomedicine [Express]* 29(8): 276-279; 1978.

The effect of 1-bromo-2-(p-ethylphenyl)-1,2-diphenylethylene (2, 20, or 200 mg/kg diet) on mammary gland development was studied in 25-day-old female C3H/f(XVII/G) mice with isologous pituitary gland implants under the kidney capsule. This graft is associated with high prolactin levels and a high incidence of mammary cancers. Fifty days after implantation, hyperplastic alveolar nodules (HAN's) were noted in the mammary glands of untreated controls. Mammary gland development was markedly inhibited in mice treated with the two higher doses of bromotriphenylethylene, and no HAN's were present. Mammary gland development in mice treated with the lowest dose was similar to that in the con-

trols. The higher doses also prevented development of the ovaries and uterine horns. (12 refs)

- 79-2017 Morphological Study of Rotenone-induced Breast Tumors in Wistar Rats.** (Eng) Merchan, J. (Depastamento de Histologia y Anatomia Patologica, Facultad de Medicina, Universidad Complutense de Madrid, Madrid, Spain); Diaz-Gil, J.; Figueras, M. A.; Navarro, M. A.; Viladiu, P.; Gosalvez, M. *Rev Esp Oncol* 25(1): 107-120; 1978.

The histological features of 20 primary and 10 transplanted mammary tumors induced in Wistar rats by rotenone (0.1 to 0.2 mg/day, 5 days/wk, for 2-3 mo) were studied. Grossly, the tumors appeared as sc masses isolated from neighboring tissues by a white, fasciculated capsule. Obesity caused by extraordinary augmentation of the perivisceral adipose tissue was noted in non-tumor-bearing rats, but not in tumor-bearing rats. Light microscopy showed three patterns of tumor growth: a mixture of epithelial and connective tissue proliferation without microscopic features of malignancy; a pattern dominated by dilated ducts filled with an amorphous eosinophilic material; and a pattern of more uniform ducts with typical secretion images upon electron microscopy. The secreting acini were similar to those observed during lactation. Greatly altered cells often had normal mitochondria, whereas at times normal cells exhibited mitochondria with highly abnormal ultrastructures. The tumors showed a moderate estrogen dependence. These tumors thus resembled those of mammary fibroadenoma and fibrocystic disease in women and might be useful for studying these lesions. (24 refs)

- 79-2018 Tumors in Mice Receiving Subcutaneous Injections of δ 9 Tetrahydrocannabinol (Meeting Abstract).** (Eng) Szepeswol, J. (Dept. Biological Sciences, Florida International Univ., Miami, FL, 33199); Fletcher, J.; Toro-Goyco, E. *Fed Proc* 38(3, part 2): 1450; 1979. (no refs)

- 79-2019 Ellipticine and Derivatives Induce Breakage of L1210 Cells DNA In Vitro.** (Eng) Paoletti, C. (205 route de Narbonne, 31078 Toulouse Cedex, France); Lesca, C.; Cros, S.; Malvy, C.; Auclair, C. *Biochem Pharmacol* 28(3): 345-350; 1979.

The effect of ellipticine (E), 9-hydroxyellipticine (OHE), 2-methyl-9-hydroxyellipticinium (CH₃OHE), and 9-aminoellipticine (NH₂E) on the DNA of L1210 cells were studied. E and several of its derivatives have been reported to be cytotoxic and antitumor agents. They also bind strongly to DNA, and most of them intercalate into DNA base pairs. None of the treated L1210 cells stained with Trypan Blue, and none of the four drugs modified the oxygen consumption of the cells. However, part of the DNA extracted from treated cells

migrated less rapidly into an alkaline sucrose gradient than the bulk of the material extracted from untreated cells, which indicates that DNA fragmentation had occurred. This effect was noted within < 1 hr of drug exposure, and if the duration of exposure was increased, the fraction of slowly moving DNA was not enhanced significantly. The minimal effective DNA-breaking dose was 1,000, 20, 100, and 500 nanograms (ng)/ml for E, OHE, CH₃OHE, and NH₂E, respectively, but the doses that inhibited the rate of in vitro cell growth by 50% were 242, 3.9, 13.8, and 53 ng/ml, respectively. Removal of DNA breaks was very rapid after exposure was discontinued. One interesting observation was the limited extent of DNA degradation (< 30% of total DNA) that occurred in the treatment cells irrespective of dose or duration of exposure. (26 refs)

- 79-2020 Lysergic Acid Diethylamide and Acute Leukemia.** (Eng) Goh, K. (435 E. Henrietta Road, Rochester, NY, 14620); Bauman, A. W. *J Am Med Wom Assoc* 33(10): 419-422; 1978.

Chromosomal breakages presumably caused by lysergic acid diethylamide (LSD) have led to the speculation that there may be an increase in the incidence of leukemia among LSD users. A 23-yr-old Caucasian man with a history of taking LSD over a period of 8 mo was diagnosed with acute myeloblastic leukemia 1.5 yr later. This is the fourth reported case of acute leukemia in a patient with a history of LSD ingestion. This low incidence may reflect underreporting of LSD usage in leukemia, a lack of direct questioning of LSD usage in leukemic patients, or lack of a cause-and-effect relationship between LSD and leukemia. (9 refs)

- 79-2021 Evidence for a Mutagenic Effect of the Narcotic Antagonist, Naltrexone, in Germ Cells of *Drosophila*.** (Eng) Zimmering, S. (Div. Biology and Medicine, Brown Univ., Providence, RI, 02912). *Mutat Res* 66(2): 129-131; 1979.

The frequency of sex-linked recessive lethals produced by the narcotic antagonist N-cyclopropylmethylnoroxymorphone (Naltrexone) in *Drosophila melanogaster* at a nontoxic dose of 10 mg/ml was 0.43%. This was significantly higher than the frequency in controls (0.16%, $p < 0.001$). Results of large-scale experiments testing for chromosome breakage and nondisjunction were negative. (5 refs)

- 79-2022 Determination of Halogenated Organic Compounds and Mutagenicity Testing of Spent Bleach Liquors.** (Eng) Bjorseth, A. (Central Inst. Industrial Res., P.O. Box 350, Oslo 3, Norway); Carlberg, G. E.; Moller, M. *Sci Total Environ* 11(2): 197-211; 1979.

The organohalogenated compounds in and mutagenicities of the spent bleach liquors used in the production of paper pulp were studied. Several organohalogenated compounds that have not been reported previously were identified in these liquors. These compounds included halogenated derivatives of dimethylpropyl naphthalenes and alkylated catechols. However, approx 70% of the total organochlorine compounds were not identified. The concentrated and unconcentrated effluents were tested for mutagenicity by the Ames Salmonella test. Weak but significant mutagenicity, especially for strain TA100, was shown by the effluent from the first chlorination stage in the sulfite process, effluents from both chlorination stages in the sulfate process, and the effluent from the hypochlorite stage in the sulfate process. All concentrated extracts, except the one from the alkali stage in the sulfite process, were mutagenic. Similar results were obtained with the cyclohexane extracts of the effluents. Dichloro-p-cymene and bromo-p-cymene were weakly mutagenic without metabolic activation. Addition of liver microsomes for metabolic activation reduced the mutagenicity of all substances tested except for the effluent from the first chlorination stage in the sulfate process. (21 refs)

79-2023 The Influence of Dietary Protein Level and 7,8-Benzoflavone on the In Vivo Covalent Binding of Benzo(a)pyrene to Liver and Lung DNA (Meeting Abstract). (Eng) Falahee, K. J. (Cornell Univ., Ithaca, NY, 14853); Campbell, T. C. *Fed Proc* 38(3, part 1): 369; 1979. (no refs)

79-2024 Synthesis of 12-Fluoro-7-methylbenz(a)anthracene and 7-Fluoro-12-methylbenz(a)anthracene. (Eng) Newman, M. S. (Dept. Chemistry, Ohio State Univ., Columbus, OH, 43210); Khanna, J. M. *J Org Chem* 44(5): 866-868; 1979.

The synthesis of 12-fluoro-7-methylbenz(a)anthracene (12-F-7-MBA) and 7-fluoro-12-methylbenz(a)anthracene (7-F-12-MBA), compounds related to 7,12-dimethylbenz(a)anthracene (DMBA), the most carcinogenic dimethylbenz(a)anthracene hydrocarbon known, is described. These compounds were synthesized in order to provide more information as to why the methyl (Me) group at position 12 in DMBA should increase the activity of 7-methylbenz(a)anthracene. It is possible that the Me at 12 is metabolized to give a more potent carcinogen, that it blocks a detoxification mechanism that occurs at 12, or the steric effect of the 12-Me group causes sufficient intramolecular overcrowding that the noncoplanar DMBA is more easily metabolized to the ultimate carcinogen. 12-F-7-MBA is the last of the monofluoro-7-MBA's to be tested. Furthermore, the testing of 12-F-7-MBA is considered particularly important because the 12-fluoro group should not only prevent any metabolism at 12, but the steric effect of the F at 12 is considerably less than that of a Me group. 7-F-12-MBA was synthesized to

determine if it is as carcinogenic as DMBA, a finding that would cast light on the mechanism by which DMBA produces cancer, because an F at position 7 would block a detoxification pathway and would make impossible a carcinogenic mechanism that involves metabolism at the 7-Me group of DMBA. 79-2025 In Vitro N-Hydroxylation of 4-Aminobiphenyl (Meeting Abstract). (Eng) Turner, J. C. (Lilly Res. Lab., Indianapolis, IN, 46206); Whitaker, G.; McMahon, R. E. *Fed Proc* 38(3, part 1): 683; 1979. (no refs)

79-2026 Chromosomal Aberration Tests on 29 Chemicals Combined with S9 Mix In Vitro. (Eng) Mat-suoka, A. (Div. Mutagenesis, Biological Safety Res. Center, Natl. Inst. Hygienic Sciences, 1-18-1 Kamiyoga, Setagaya-ku, Tokyo 158, Japan); Hayashi, M.; Ishidate, M. *Mutat Res* 66(3): 277-290; 1979.

A metabolic activation system consisting of a rat liver microsome fraction plus cofactors (S9 mix) was incorporated in an in vitro chromosome aberration test for screening environmental chemical mutagens/carcinogens. Chinese hamster lung (CHL) cells were incubated with 1 of the 29 chemicals evaluated in the presence or absence of S9 mix. The test chemicals included 4 dialkylnitrosamines, 9 additional compounds known to be procarcinogens, 8 pharmaceutical drugs, 2 pesticides, 3 food additives, and 3 industrial chemicals. The dialkylnitrosamines only induced chromosome aberrations when they were treated with S9 mix. The incidence of chromosome aberrations varied with incubation time, recovery time, components of the S9 mix, and the agent used to induce the microsomal enzymes (polychlorinated biphenyl, phenobarbital, or 3-methylcholanthrene). For dimethylnitrosamine, max incidence was obtained when the cells were incubated with S9 mix for 3 hr and harvested 24 hr after treatment. Therefore, this procedure was routinely applied to the remaining chemicals. Ten of 16 known carcinogens induced aberrations when they were treated with S9 mix. The remaining six carcinogens induced few or no aberrations even after activation. The two insecticides, allethrin and diazinon, were strongly positive at relatively low doses only when they were activated with the S9 mix. Three drugs, ethenzamide, methyl p-hydroxybenzoate, and nitrofurazone, and the food additive sodium hypochlorite were positive on activation. The two industrial chemicals, styrene monomer and tris-dichloropropylphosphate, were also positive in this activation system. This assay is concluded to be useful for screening environmental mutagens/carcinogens. Chemicals that were positive in the assay should be regarded as being suspicious and should be tested further in animals. (25 refs)

79-2027 Comparison of Metabolism-mediated Binding to DNA of 7-Hydroxymethyl-12-methylbenz(a)anthracene and 7,12-Dimethylbenz(a)anthracene. (Eng) Dipple, A. (Molecular Aspects Chemical Carcinogenesis, Frederick Cancer Res. Center, P.O. Box B, Frederick, MD, 21501); Tomaszewski, J. E.; Moschel, R. C.; Bigger, C. A.; Nebzzydowski, J. A.; Egan, M. *Cancer Res* 39(4): 1154-1158; 1979.

The binding of 7-hydroxymethyl-12-methylbenz(a)anthracene and 7,12-dimethylbenz(a)anthracene (DMBA) to DNA catalyzed by mouse embryo cells or by rat liver microsomes was studied to determine if the metabolic activation of DMBA for DNA binding involves an initial conversion to a 7-hydroxymethyl derivative. The binding of DMBA to the DNA of mouse embryo cells in culture was an order of magnitude greater than that of the hydroxy compound throughout a dose range up to 0.1 µg hydrocarbon/ml of medium. The 7-hydroxymethyl derivative and DMBA formed nucleoside adducts that exhibited different chromatographic and fluorescence spectral properties. There was no indication, in the analysis of the DMBA products, of any product that might have arisen from the further metabolism of any hydroxymethyl derivative generated by metabolism. It is concluded that the hydroxy compound is not an intermediate in the binding of DMBA to DNA in these systems. The binding of the hydroxymethyl derivative to DNA was inhibited by 1,1,1-trichloropropylene 2,3-oxide, an inhibitor of epoxide hydrazase. This result and the fluorescence spectra of the hydroxy compound-DNA adducts indicate that the hydroxy compound is activated for DNA binding through the formation of a diol-epoxide in the 1,2,3,4-ring. As previously demonstrated for DMBA, this is consistent with the activation of the hydroxy compound through a bay-region diol-epoxide. (26 refs)

79-2028 Distribution of 7,12-Dimethylbenz(a)anthracene (DMBA) in Serum Proteins, In Vivo (Meeting Abstract). (Eng) Penn, A. (New York Univ., Inst. Environmental Medicine, New York, NY, 10016); Dreessen, M.; Batastini, G. *Fed Proc* 38(3, part 2): 1063; 1979. (no refs)

79-2029 Mutagenic Effect of 7,12-Dimethylbenz(a)anthracene-epidioxide on *Salmonella typhimurium*. (Eng) Tu, M. H. (Northwestern Univ. Dental Sch., Chicago, IL, 60611); Perry, D.; Chen, C. *Mol Pharmacol* 15(1): 189-191; 1979.

A modified Ames mutagenicity assay in which light was used for activation instead of liver microsomes was chosen as a preliminary screening device to determine whether 7,12-dimethylbenz(a)anthracene-7,12-epidioxide (DMBAO₂) can be an ultimate carcinogen. Incubation of *Salmonella typhimurium* TA100 with 7,12-dimethylbenz(a)anthracene (DMBA) in the absence of light resulted in an increased frequency of mutation. Light alone also caused some revertants.

Increased reversion was observed with increased light exposure and DMBA concentration until lethality exceeded mutagenesis. DMBAO₂ exposed to light for 24 hr was no more mutagenic than light alone, although 48 hr exposure to light rendered it more lethal. The data suggest that the bioactivated ultimate mutagen of DMBA could be DMBAO₂ and that light can activate a mutagen in situ to a specific reactive compound. (9 refs)

79-2030 Metabolism of Benzo[a]anthracene to Its Tumorigenic 3,4-Dihydrodiol. (Eng) Thakker, D. R. (Section Oxidation Mechanisms, Lab. Chemistry, Natl. Inst. Arthritis, NIH, Bethesda, MD, 20014); Levin, W.; Yagi, H.; Ryan, D.; Thomas, P. E.; Karle, J. M.; Lehr, R. E.; Jerina, D. M.; Conney, A. H. *Mol Pharmacol* 15(1): 138-153; 1979.

High-pressure liquid chromatography was used to analyze the products of the metabolism of benz(a)anthracene (BA) by rat liver microsomes and by a highly purified and reconstituted monooxygenase system. Metabolism of BA by purified cytochrome P-448 or liver microsomes from untreated, phenobarbital-treated, or 3-methylcholanthrene-treated rats yielded primarily BA 5,6-dihydrodiol and a mixture of BA 3,4-, 8,9-, and 10,11-dihydrodiols in the presence of epoxide hydrazase (EH); only trace amounts of phenols were formed. In the absence of EH, only phenols and the K-region 5,6-oxide were formed. In the presence of EH, max metabolism was 40%, whereas in the absence of EH, max metabolism was 9%. BA 5,6-oxide was a poor inhibitor of BA metabolism, 8- and 9-hydroxy-BA were moderate inhibitors (26% and 35% inhibition, respectively), and 5- and 6-hydroxy-BA were strong inhibitors (88%-89% inhibition). Unidentified phenols or non-K-region arene oxides derived from the parent hydrocarbon were responsible for the observed inhibition. The data indicate that the low carcinogenicity of BA may be explained at least in part by the low percentage of the highly tumorigenic BA 3,4-dihydrodiol formed among the metabolites of BA. (69 refs)

79-2031 Prophylactic Effect of BCG Cell-Wall Skeleton on the Tumor Induction by 7,12-Dimethylbenz[a]anthracene in Mice: Strain Difference. (Eng) Ikegami, R. (Dept. Oncogenesis, Osaka Univ. Medical Sch., Fukushima 1-1-50, Fukushima-ku, Osaka 553, Japan); Takatsu, K.; Ono, S.; Hamaoka, T.; Fujiwara, H.; Kitagawa, M.; Azuma, I.; Yamamura, Y. *Gann* 70(1): 101-107; 1979.

The effect of oil-attached BCG cell-wall skeletons (BCG-CWS, 100 µg given iv every 2 wk for 14 wk) on the tumorigenicity of 7,12-dimethylbenz(a)anthracene (DMBA, 500 µg given sc 7 days after the first BCG-CWS injection) was studied in various strains of mice. BCG-CWS significantly reduced DMBA carcinogenesis in male ddO mice, but it had no effect on the histologic appearance of the tumors (all

were squamous cell carcinomas). BCG-CWS injected sc into the site of DMBA injection was also effective, whereas ip administration was not. When given 3 to 7 wk after DMBA, BCG-CWS was less or noneffective in reducing tumor incidence. Tumor growth was significantly reduced in C57BL/6 and BALB/c mice by BCG-CWS treatment, but the same treatment had little effect in BTK and C3H/He mice. Thus, although BCG-CWS treatment (by an appropriate route and timing) appears to be effective in reducing DMBA carcinogenesis, the effectiveness varies in different strains of mice. (20 refs)

- 79-2032 Tumor Initiators and Promoters in the Induction of Epstein-Barr Virus.** (Eng) zur Hausen, H. (Institut für Virologie, Zentrum für Hygiene, Universität Freiburg, Hermann-Herder-Strasse 11, 7800 Freiburg, W. Germany); Bornkamm, G. W.; Schmidt, R.; Hecker, E. *Proc Natl Acad Sci USA* 76(2): 782-785; 1979.

The effect of various tumor initiators and promoters on the induction of Epstein-Barr virus (EBV) in different lymphoblastoid cell lines was analyzed. Neither five polycyclic aromatic hydrocarbons [including the potent tumor initiator 7,12-dimethylbenz(a)anthracene] nor the potent (ultimate) hepatocarcinogen N-acetoxy-N-2-acetylaminofluorene induced EBV. A series of compounds representing three classes of tumor-promoting diterpene esters (eg, 12-O-tetradecanoylphorbol-13-acetate) efficiently induced EBV in persistently infected cells. The concentration required for max induction ranged between 0.5 and 100 nanomolar. Some nonpromoting diterpenes (phorbol, 4 α -phorbol-12,13-didecanoate, and ingenol) did not induce EBV. However, the nonpromoters resiniferatoxin and 12-deoxyphorbol-13-decatrienoate were effective, whereas anthralin, a tumor promoter, was not. In three lines of EBV genome-carrying cells (Raji, NC-37, and RPMI 64-10), only abortive induction was noted, leading exclusively to the synthesis of early antigen. When lines with low spontaneous virus release (P3HR-1, B95-8, and QIMR-Wil) were treated with tetradecanoylphorbol acetate, approx 20-40 times more viral DNA was recovered compared with the amount in untreated controls. Viral DNA from tetradecanoylphorbol acetate-induced cultures had the same restriction endonuclease cleavage pattern as viral DNA obtained from noninduced cells. Within 10 days after induction, release of infectious virus increased approx by one order of magnitude. Prostaglandins, reported to be released after treatment with tumor promoters, were ineffective in inducing virus under the conditions tested. (23 refs)

- 79-2036 On the Biochemical Mechanism of Tumorigenesis in Mouse Skin. IX. Interrelation Between Tumor Initiation by 7,12-Dimethylbenz(a)anthracene and the Activities of Epidermal Arylhydrocarbon Monooxygenase and Epoxide Hydratase.** (Eng) Pyerin, W. G. (Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg, Germany); Hecker, E. *Z Krebsforsch* 93(1): 7-30; 1979.

The effects of 7,8-benzoflavone (BF), 2-diethylaminoethyl-2,2-diphenylvalerate HCl (SKF 525-A), and phenobarbital (PB) on tumor initiation by topical 7,12-dimethylbenz(a)anthracene (DMBA) and on arylhydrocarbon hydroxylase (AHH) and epoxide hydratase (EH) activities were studied in female NMRI mice. SKF 525-A, a selective inhibitor of cytochrome P-450, and PB, an inducer of cytochrome P-450, had no effect on DMBA tumor initiation, whereas BF, a selective inhibitor of cytochrome P-448, reduced tumor yield by up to 30% when applied with or up to 7 hr after DMBA. DMBA caused a dose-dependent increase in tumor yield and in the specific activity of epidermal AHH, but it did not affect the specific activity of EH. Topical PB had no effect on AHH activity, whereas SKF 525-A and BF reduced AHH activity up to 30% within 2-4 hr following the application of SKF 525-A or BF, but it increased to >200% of control values at 24 hr after the application of BF. None of the test compounds affected the specific activity of EH. Comparison of the time-dependence of the inhibition of tumor initiation by BF and of the DMBA-induced increase in AHH activity indicated that the effects of DMBA on tumor initiation and AHH induction were unrelated. - 79-2037 Effects of 13 *cis* and all *trans* Retinoic Acid on the Development of Bladder Cancer in Rats** (Meeting Abstract). (Eng) Tannenbaum, M. (Columbia Univ., New York, NY, 10032); Tannenbaum, S.; Richelo, B. N.; Trown, P. W. *Fed Proc* 38(3, part 2): 1073; 1979. (no refs)

- 79-2038** Age as a Modifying Factor of 7,12-Dimethylbenz(a)anthracene-induced Mammary Carcinogenesis in the Lewis Rat. (Eng) Haslam, S. Z. (Lady Davis Inst. Medical Res., Jewish General Hosp., Montreal H3T 1E2, Canada). *Int J Cancer* 23(3): 374-379; 1979.

The influence of age at 7-12-dimethylbenz(a)anthracene (DMBA) administration on mammary tumorigenesis and regression was studied in female Lewis rats. Two classes of tumor were found after DMBA treatment (single intragastric dose of 15 mg/100 g): progressively growing tumors (PGT) and spontaneously regressing tumors (SRT). Both were first palpable 2-3 mo after treatment, but the SRT never exceeded a diameter of 1 cm and they regressed to a nonpalpable state. A total of 156 PGT and SRT tumors developed, 153 of them adenocarcinomas. PCT developed throughout the 12-mo experimental period, reaching a final incidence rate of 55%-84%. PGT incidence, mean latent period of PGT development, mean numbers of PGT per PGT-bearing rat, and the relative proportion of PGT that were ovary-dependent tumors (ODT: 65%-91%) were similar for all age groups at the end of 12 mo. Twenty-five percent to 39% of ODT that initially regressed after ovariectomy subsequently resumed progressive ovary-independent growth; this occurred with similar frequency in all age groups. In contrast to PGT, the incidence of SRT was significantly higher in rats given DMBA at 25 days of age (25D) than in those treated at 50D, 70D, or 200D, and the mean latent period was significantly shorter in the 25D and 50D groups. SRT did not occur in the 90D and 150D groups. Subsequent to an initial regression, 25%, 15%, and 40% of SRT regrew in the 25D, 50D, and 200D groups, respectively. Eighty percent, 50%, and 75% were ODT in the 25D, 50D, and 200D groups, respectively. The results indicate that age is a modifying factor in DMBA-induced mammary carcinogenesis in Lewis strain rats. It affected the number of SRT induced, the latent period of SRT development, and the number of tumors that regressed spontaneously. However, it does not confer significant or permanent refractoriness. (26 refs)

- 79-2039** Identification of 7,12-Dimethylbenz(a)anthracene Metabolites That Lead to Mutagenesis in Mammalian Cells. (Eng) Huberman, E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 20014); Chou, M. W.; Yang, S. K. *Proc Natl Acad Sci USA* 76(2): 862-866; 1979.

An attempt was made to identify the metabolites that are responsible for 7,12-dimethylbenz(a)anthracene (DMBA) mutagenicity in mammalian cells and to determine by high-pressure liquid chromatography the type of DMBA metabolites that are produced in intact cells. The mutagenicity of DMBA and 11 of its enzymatically derived metabolites was tested with Chinese hamster V79 cells. The metabolites consisted of 7-hydroxymethyl-12-methylbenz(a)anthracene (I), 7-methyl-12-hydroxymethylbenz(a)anthracene (II), and 7,12-dihydroxymethylbenz(a)anthracene and 3 trans-3,4-diols, 2 trans-5,6-diols, and 3 trans-8,9-diols, all of which were

derived from DMBA or the hydroxymethyl derivatives. Mutations were characterized by resistance to ouabain (OB) and 6-thioguanine (TG). None of the tested metabolites were mutagenic in V79 cells, which do not metabolize polycyclic aromatic hydrocarbons. Therefore, mutagenesis in the V79 cells was tested in the presence of golden hamster cells capable of metabolizing polycyclic aromatic hydrocarbons (cell-mediated assay). In this assay, DMBA, metabolites I and II, and their trans-3,4-diols were mutagenic for both genetic markers, and the mutagenic response increased as a function of hydrocarbon dose. All other metabolites were either inactive or showed up to a four-fold higher mutation frequency than the untreated V79 cells for OB and TG resistance. The DMBA-trans-3,4-diol was the only metabolite that was more active than DMBA itself; at 0.05 μ M it was six to eight times more active than DMBA in inducing both OB and TG resistance. This diol was also mutagenic at 0.01 μ M. Mutagenesis by DMBA and the trans-3,4-diols was inhibited by 7,8-benzoflavone, an inhibitor of mixed-function oxidases. Analysis of DMBA metabolism in intact golden hamster cells indicated that DMBA-trans-3,4-diol is one of the major metabolites produced. DMBA-trans-3,4-diol may be metabolized to a diol-epoxide, presumably the trans-3,4-diol-1,2-epoxide, which may be a major reactive metabolite responsible for DMBA mutagenicity in mammalian cells. (58 refs)

- 79-2040** Systemic Two-Stage Carcinogenesis in the Epithelium of the Forestomach of Mice Using 7,12-Dimethylbenz(a)anthracene as Initiator and the Phorbol Ester 12-O-Tetradecanoylphorbol-13-acetate as Promoter. (Eng) Goerttler, K. (German Cancer Res. Center, Inst. Experimental Pathology, Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Loehrke, H.; Schweizer, J.; Hesse, B. *Cancer Res* 39(4): 1293-1297; 1979.

Systemic tumor initiation-promotion was investigated in the forestomach epithelium of female C57BL/6 mice. Fifty mice were treated intragastrically with a single dose of 7,12-dimethylbenz(a)anthracene (DMBA: 50 mg/kg) followed 1 wk later by repeated intragastric administration of the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA: 10 mg/kg 2x/wk for 35 wk). Forty-five of the 50 DMBA + TPA-treated animals developed tumors of the forestomach, compared with 0/50 untreated mice and 0/50 TPA-treated mice. Ten of 50 mice treated with DMBA alone developed forestomach tumors. DMBA + TPA-treated mice also developed tumors in other sites (skin, lip, thymus, lung, ovary, and hematopoietic system). The applicability of the two-stage experiment to the mouse forestomach is indicative of a preference of the DMBA-TPA combination for keratinizing epithelial tissues. (34 refs)

- 79-2041** Characteristics of Benzo(a)pyrene Metabolism by Kidney, Liver, and Lung Microsomal Frac-

tions from Rodents and Humans. (Eng) Prough, R. A. (Dept. Biochemistry, Univ. Texas Health Science Center at Dallas, Dallas, TX, 75235); Patrizi, V. W.; Okita, R. T.; Masters, B. S.; Jacobsson, S. W. *Cancer Res* 39(4): 1199-1206; 1979.

The kinetics of benzo(a)pyrene (BP) metabolism by microsomal fractions (MF) of liver and lung of rats, hamsters, and humans was studied by high-pressure liquid chromatography (HPLC). The formation of total BP metabolites (dihydrodiols, quinones, 4,5-oxides, and phenols) by liver MF from rats or hamsters pretreated with corn oil, phenobarbital (PB), or 3-methylcholanthrene (3-MC) was nonlinear with time beyond 2 min at low protein concentrations (0.3 mg/ml). However, human liver MF catalyzed BP metabolism that was linear up to 10 min at protein concentrations of 1-5 mg/ml. Hamster and rat lung MF metabolized BP at 0.5% of the rate of liver MF; the rate of metabolite formation was increased only by 3-MC pretreatment. The kinetics of metabolism by hamster and rat lung MF was linear up to 15 min. The MF from human kidney and lung were stable to freezing and had metabolic activities that were 40%-60% of those obtained with rodent lung. Liver activity, however, decreased 30%-40% during the first 14 hr of freezing. Human liver MF (unfrozen) had activities that were one-sixth those of the rodent liver. Persons who had ingested large doses of barbiturates before death had significantly higher levels of BP metabolism activity; no correlation was detected between liver or lung monooxygenase activity and smoking habits. Analysis of the product distribution of the benzo-ring metabolites showed that the human lung MF catalyzed the formation of a significantly higher proportion of benzo-ring metabolites than did other human or rodent organs, with the possible exception of hamster lung. (50 refs)

79-2042 Cell Sorter Analysis of Carcinogen Metabolites in Human Tissues. (Eng) Tyrer, H. W. (Becton, Dickinson Res. Center, Research Triangle Park, NC, 27709); Adams, L. A.; Tiffany, S. M.; O'Connell, J. P.; Cantrell, E. T. *J Histochem Cytochem* 27(1): 508-511; 1979.

A fluorescence-activated cell sorter (FACS-II) was used to study biochemical parameters in a heterogeneous population of cultured normal human lymphocytes. Some cultures were treated with 10 μ l benz(a)anthracene (BA). Cell sizes varied in phytohemagglutinin-activated cultures, with the larger cells containing more benzo(a)pyrene hydroxylase (BPOH) activity than the smaller cells. Among cells of a given size, BPOH activity was greater in those exposed to BA during culture than in untreated controls. When BA-induced lymphocytes were sorted into four subgroups according to size, the specific activity of ethoxyresorufin O-deethylation was greater in the larger cells than in the smaller cells. The technique of sorting before enzyme assay can be applied to cell types and enzyme reactions that cannot otherwise be measured directly. (10 refs)

79-2043 Benzo(a)pyrene Uptake by Human Plasma Lipoproteins In Vitro. (Eng) H. P. Shu (Donner Lab., Univ. California, Berkeley, CA, 94720); Nichols, A. V. *Cancer Res* 39(4): 1224-1230; 1979.

The in vitro uptake of benzo(a)pyrene (BP) by human plasma lipoproteins (LP) was studied using blood samples from healthy male donors (40-58 yr old). 14 C-BP was incubated in whole blood, plasma, or isolated LP fractions. BP distribution between plasma and RBC was estimated following sedimentation of RBC, and BP distribution in the major LP fractions was determined following ultracentrifugal fractionation of plasma. More than 70% of the BP was distributed in the plasma. Of the BP in plasma, <5% partitioned into the bulk of the plasma proteins [density (d) > 1.21 g/ml], >95% into plasma LP (d < 1.21 g/ml). BP distribution in normolipoproteinemic plasma was 29% in very-low-density, 57% in low-density, and 10% in high-density LP. The percentage of BP distribution among LP fractions was independent of the level of BP uptake by plasma. It was also independent of whether the incubation was conducted with total plasma that was subsequently fractionated into LP fractions or with isolated LP fractions. BP uptake by LP's was correlated with LP-total lipid volume for isolated very-low-density, low-density, and high-density LP's. BP incorporated into chylomicrons or isolated LP fractions transferred from chylomicron to LP and among LP, respectively. It is speculated that if BP is transported by the various LP classes in vivo, they may play a role in the cellular uptake of BP. Cellular uptake may involve simple partitioning of BP between the plasma LP's and the cell membrane lipid volume. Alternatively, cellular uptake of BP may proceed by a more specific process involving cell receptors. (24 refs)

79-2044 Preliminary Data on the Carcinogenic Effects of Adriamycin and Daunomycin in Male and Female Sprague-Dawley Rats. (Ita) Bucciarelli, E. (Cattedra di Anatomia Umana Normale, Universita degli Studi Urbino, Urbino, Italy); Provvienza, M.; Santori, P.; Vespasiani, G. *Lav Ist Anat Istol Patol Perugia* 38(2): 71-81; 1978.

The carcinogenicity of adriamycin and daunomycin (single 10-mg/kg doses in physiological saline solution iv) was studied in 1-mo-old virgin male and female Sprague-Dawley rats. Daunomycin induced breast tumors in 18/28 females (26 tumors: 24 adenocarcinomas and 2 fibroadenomas) and in 10/27 males (10 tumors: 9 adenocarcinomas and 1 fibroadenoma). The induction times were 36-213 days (median 80) in the females, and 39-196 days (median 83) in the males. Adriamycin induced 18 tumors (13 adenocarcinomas and 5 fibroadenomas) in 10/35 females after 90-206 days (median 135). No tumors developed in the 57 males. Three adenocarcinomas were found in 3/25 untreated control females after 114-360 days (median 220). The results suggest that hormonal factors are involved in the induction of breast tumors by adriamycin and daunomycin. (26 refs)

79-2045 Role of Inflammatory-Cell Proteases as Amplifiers of Chemical Promoters (Meeting Abstract). (Eng) Ranney, D. F. (Dept. Pathology, Univ. Texas Health Science Center, Dallas, TX, 75235); Quattrone, A. J. *Fed Proc* 38(3, part 2): 1073; 1979. (no refs)

79-2046 Inhibition of Functional and Morphological Differentiation of Cultured Mouse Myeloid Leukemia Cells by Tumor Promoters. (Eng) Kasukabe, T. (Dept. Chemotherapy, Saitama Cancer Center Res. Inst., Ina-machi, Kitaadachi-gun, Saitama-ken 362, Japan); Honma, Y.; Hozumi, M. *Gann* 70(1): 119-123; 1979.

The ability of 12-O-tetradecanoylphorbol 13-acetate (TPA) and related plant diterpenes to inhibit the induction of differentiation of biopotential mouse myeloid leukemia M1 cells into mature (phagocytic) macrophages and granulocytes was studied. First, the effects of TPA on the dexamethasone (DM)-induced phagocytic activity of M1 cells were determined. The phagocytic activity of M1 cells was reversibly inhibited by (DM: 10^{-7} M) plus TPA (1.6×10^{-8} M), but not by TPA alone. The degree of inhibition was dependent on the relative concentrations of both compounds. TPA (8×10^{-10} M) also inhibited 68% of the phagocytic activity of M1 cells induced by a 5% protein inducer. Phorbol 12,13-didecanoate (PDD: 1.6×10^{-7} M) was less a potent inhibitor of phagocytic activity than was TPA, and 4 α -phorbol 12,13-didecanoate and phorbol had no inhibitory effects. The inhibition of DM-induced phagocytic activity was not due to general cytotoxicity. TPA inhibited the induction of morphological differentiation of M1 cells by either DM or a 1% protein inducer. The data demonstrate that TPA and related plant diterpenes with tumor-promoting activity reversibly inhibit the induction of functional and morphological differentiation of M1 cells by DM or a protein inducer. 79-2051 The Mutagenic Activity of Halogenated Compounds Found in Chlorinated Drinking Water. (Eng) Simmon, V. F. (Microbial Genetics Program, Stanford Res. Inst. International, Menlo Park, CA, 94025); Tardiff, R. G. *Water Chlorination* 2: 417-431; 1978.

The mutagenic activities of 22 halogenated compounds found in chlorinated drinking water were determined using the Ames *Salmonella*/microsome procedure with *S. typhimurium* strains TA1535 and TA100. Two known carcinogens, carbon tetrachloride and chloroform, were not mutagenic in this system, probably because mutagenic metabolites were formed in insufficient amounts or they were so unstable that they did not survive long enough to penetrate the bacteria and interact with the DNA. Known carcinogens that were mutagenic were vinyl chloride, vinylidene chloride, 1,2-dichloroethane, 1,1,2-trichloroethylene, bis(2-chloroethyl)ether, methyl iodide, and bromoform. Mutagenic activity was also observed with bromodichloromethane, chlorodibromomethane, methylene bromide, bromochloromethane, methylene chloride, methyl bromide, methyl chloride, 2-chloropropane, 1-chloropropene, bis(2-chloroisopropyl)ether, n-butyl bromide, t-butyl bromide, and s-butyl bromide. The results indicate that the number and amount of alkyl halides in potable water should be reduced to lessen possible health hazards. (20 refs)

79-2052 Photochemical and Biological Implications of the Atmospheric Reactions of Amines and Benzo(a)pyrene. (Eng) Pitts, J. N. (Statewide Air Pollution Res. Center and Dept. Chemistry, Univ. California, Riverside, CA, 92521). *Phil Trans R Soc Lond* 290(1376): 551-576; 1979.

The reactions of benzo(a)pyrene (BP) and its nonmutagenic isomer perylene in simulated and real urban atmospheres, the reactions of mixtures of simple aliphatic amines and nitrogen oxides in air containing traces of nitrous acid (HONO), and the mutagenicity of ambient urban particles were studied. The Ames assay was used to screen for mutagenic activity in particulate samples from urban atmospheres. The samples exhibited frameshift but not base-pair substitution mutations,

and there was no requirement for metabolic activation. Exposure of BP in the dark to the gases in ambient smog resulted in the formation of direct-acting frameshift mutagens with no base-pair substitution activity. Perylene and pyrene formed mutagens under similar conditions. These reactions might account for part of the carcinogenicity of organic particulates collected from smog and exhausts of spark ignition and diesel engines. At < 1 ppm, diethylamine and triethylamine (DEA and TEA) readily formed photochemical smog in outdoor chambers. Small but significant amounts of diethylnitrosamine (DEN) were formed in the dark from DEA, but they were destroyed in sunlight. In contrast, DEN was initially formed upon irradiation of TEA-nitrogen oxide mixtures and then it photodecomposed. Other significant nitrogenous compounds formed in sunlight include dialkylnitramines and substituted amides; small amounts of acetamide were present in the particulate phase from DEA and TEA. 79-2053 Metabolism of Benzo(a)pyrene by Multinucleated Giant Cells. (Eng) Bockman, D. E. (Dept. Anatomy, Medical Coll. Georgia, Augusta, GA, 30902); Black, O.; Webster, P. D. *J Reticuloendothel Soc* 25(1): 39-47; 1979.

The ability of benzo(a)pyrene (BP) crystals (1 or 5 mg) implanted on the surface of pancreas for periods of 1-8 mo to induce pancreatic tumors was studied in 123 male and female Long-Evans rats. Yellowish granular deposits were observed in the regions of the original implant at all times. Large complexes composed of multinucleated giant cells, macrophages, and a narrow peripheral band of connective tissue cells and fibers were arranged around the crystals. The giant cells occupied spaces previously occupied by other BP crystals, and they contained numerous organelles that were usually dispersed uniformly close to the cell membrane bordering the central BP crystals. Extremely small bits of BP crystal were also seen deeper in the cytoplasm of these cells, and the periphery of each giant cell was frequently characterized by elaborate interdigitating cellular processes bordering areas of connective tissue. Carcinomas were not observed, but acute and chronic reactive cells were frequently present. The implant region sometimes became adherent to another organ. Occasionally, an abscess developed. The pancreas frequently showed chronic inflammation and accumulations of tubular complexes similar to those present during tumor induction by 7,12-dimethylbenz(a)anthracene. (16 refs)

79-2054 3,4-Benzopyrene and Perylene in Mussels, *Mytilus* SP. from the Laguna Veneta, Northeast Italy. (Eng) Fossato, V. U. (Istituto di Biologia del Mare, Consiglio Nazionale delle Ricerche, Riva Sette Martiri 1364/A, Venezia 30122, Italy); Nasci, C.; Dolci, F. *Mar Environ Res* 2(1): 47-53; 1979.

Mussels collected bimonthly during July 1975 to November 1976 from the Laguna Veneta in northeastern Italy and the adjacent Adriatic sea were analyzed for benzo(a)pyrene (BP) and perylene (Pe) levels. Mean concentrations of BP and Pe were generally in the range 12.0-135.1 and 1.5-16.9 $\mu\text{g/kg}$ dry wt, respectively, but values as high as 327 $\mu\text{g/kg}$ for BP and 71 $\mu\text{g/kg}$ for Pe were obtained. The highest concentrations were usually found in mussels taken from waters adjacent to the industrial port area and within the city of Venice and in an area limited to the fishing port of Chioggia. The lowest levels were found in mussels from the Adriatic Sea and in the central basin of the Laguna Veneta, areas furthest from the industrial and urban areas. The ratio of BP to Pe was always close to 7.3, indicating a common major source for these pollutants (most probably associated with the combustion of fossil fuels). A gradient of contamination was demonstrated, with concentrations decreasing with distance from the source of pollution. Similar results were obtained in a previous study of aliphatic hydrocarbon contamination of mussels in this area. Max concentrations of BP and Pe were found in mussels taken in May and July. The degrees of contamination observed probably do not represent a serious human health hazard. (20 refs)

- 79-2059** The Metabolic Activation of Benzo(a)pyrene and 9-Hydroxybenzo(a)pyrene by Liver Microsomal Fractions. (Eng) Lubet, R. A. (Dept. Biochemistry, Univ. Texas Health Science Center, 5323 Harry Hines Blvd., Dallas, TX, 75235); Capdevila, J.; Prough, R. A. *Int J Cancer* 23(3): 353-357; 1979.

The microsome-mediated *Salmonella typhimurium* assay was used to compare the metabolic activation of benzo(a)pyrene (BP) and 9-hydroxybenzo(a)pyrene (9-hydroxy-BP) to mutagenic and alkylating moieties by liver microsomes from 5,6-benzoflavone (BF)-pretreated male Sprague-Dawley CD rats. 9-Hydroxy-BP was 1.75 times more mutagenic than BP in this system. Studies of the binding of BP and 9-hydroxy-BP to exogenous calf thymus DNA in the presence of microsomes from BF-pretreated rats showed that 9-hydroxy-BP was significantly more effective than BP, yielding almost six times more DNA-bound hydrocarbon. Trichloropropene-2,3-oxide increased the mutagenicity of BP by almost 60% and increased the microsome-mediated binding of BP to DNA by 100%. However, it had little effect on the mutagenicity of, or DNA alkylation by, 9-hydroxy-BP. BF substantially inhibited both BP- and 9-hydroxy-BP-mediated mutagenesis and alkylation in a concentration-dependent fashion. (24 refs)

- 79-2063** Uptake and Excretion of Benzo(a)pyrene and Its Metabolites by the Rat Pancreas. (Eng) Iqbal, Z. M. (Sch. Public Health, Univ. Illinois at Medical Center, P.O. Box 6998, Chicago, IL, 60680); Yoshida, A.; Epstein, S. S. *Drug Metab Dispos* 7(1): 44-48; 1979.

The uptake and excretion of benzo(a)pyrene (BP) in the rat pancreas were investigated and compared with uptake and excretion in the liver and bile. Following the iv administration of [³H]BP (0.9 ml plasma containing 9.99×10^7 disintegrations/min) to male Sprague-Dawley rats, uptake of radioactivity by the pancreas (per gram of tissue) was approx 16% of that in the liver. At 5 min following administration, unmetabolized BP in the pancreas, liver, and blood constituted 79%, 50%, and 49% of total BP uptake, respectively. The total uptake and unmetabolized BP in these tissues declined in a biphasic manner over the 2-hr observation period, during which only 0.30% of the total administered dose was excreted in pancreatic juice, compared with 39% in bile. All radioactivity in pancreatic juice and bile was due to polar BP metabolites, including 3-hydroxy-BP. Methylcholanthrene pretreatment (20 mg/kg, ip) induced a significant increase ($p < 0.005$) in biliary, but not pancreatic, excretion of radioactivity. The administration of secretin and pancreozymin caused a twofold increase ($p < 0.001$) in pancreatic, but not biliary, radioactivity. It appears that pancreatic acinar and ductal cells could easily be exposed to carcinogenic BP metabolites of hepatic origin either during biliary excretion or following transportation to the pancreas by the blood. Accumulation of carcinogenic metabolites in the pancreas, combined with prolonged cellular exposure, may be relevant to an understanding of BP carcinogenicity in the rat. (36 refs)

- 79-2067 Benzo[a]pyrene Metabolism by Hepatic and Extrahepatic Tissues in Streptozotocin-diabetic Rats.** (Eng) Stohs, S. J. (Dept. Biomedical Chemistry, Coll. Pharmacy, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE, 68105); Reinke, L. A.; Hassing, J. M.; Rosenberg, H. *Drug Metab Dispos* 7(1): 49-51; 1979.

Microsomal benzo(a)pyrene (BP) metabolism was studied in the liver, lung, kidney, and adrenal gland of Sprague-Dawley female rats 7 or 10 days following the induction of diabetes in these animals with streptozotocin (60 mg/kg, iv). BP metabolism in hepatic microsomes was increased by 75% compared with that in controls ($p < 0.05$), and cytochrome P-450 levels were similarly increased ($p < 0.005$). BP monooxygenase activity in the intestinal microsomes was approx 2.7 times that of control rats ($p < 0.005$), whereas BP monooxygenase activity in the lung microsomes was decreased by 40% ($p < 0.005$). No significant changes in BP metabolism were observed in the kidney or adrenal tissues of diabetic animals. Changes in hepatic, intestinal, and lung microsomal enzyme levels normalized following insulin administration, suggesting that altered BP metabolism results from the diabetic state and not as a direct effect of streptozotocin. The dramatic reduction in BP metabolism by lung microsomes, in contrast to the stimulatory effect of diabetes on the BP monooxygenase activity in the intestine and liver, suggests that there are separate regulatory mechanisms for BP monooxygenase in lung and liver. The lung metabolism of drugs, endogenous substrates, and other xenobiotics may be impaired in the diabetic state. (31 refs)

- 79-2068 Genetic Differences in the Binding of Benzo(a)-pyrene Metabolites to DNA in the Mouse.** (Eng) Boobis, A. R. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD, 20014); Kouri, R. E.; Nebert, D. W. *Cancer Detect Prev* 2(1): 83-111; 1979.

Genetic differences in the binding of benzo(a)pyrene (BP) metabolites to DNA were assessed in female C3H, C57BL/6, and DBA/2 mice. When the mice were inoculated sc with 150 μ g BP, the carcinogenic index (CI: % tumor incidence/av latency, $\times 100$) for C3H was > 5 times greater than that for C57BL/6 and about 15 times greater than that for DBA/2. Sephadex LH20 column chromatography of an enzyme digest of DNA with 3 H-BP metabolites bound during in vitro incubation with hepatic microsomes from 3-methylcholanthrene-treated mice of all three strains revealed that nine peaks, representing BP metabolites bound to DNA nucleosides (NS), could be identified reproducibly. When C3H or C57BL/6 was compared with DBA/2, a positive general correlation was found between CI in vivo and the size of 8/9 peaks, hepatic aryl hydrocarbon hydroxylase activity, and total hepatic cytochrome P-450 content. Peaks D, E, H, and I demonstrated relative differences among the three strains that were in the same direction as the CI; ie, the C3H peaks were greater than the C57BL/6 peaks, and both were consid-

erably greater than the DBA/2 peaks. However, no such correlation was found when C3H was compared with C57BL/6. Hence, the total quantity of NS-BP metabolite complexes in each of the nine peaks was not necessarily associated with the CI. A defect in the general immune competence of C3H may be an important factor in its markedly increased susceptibility to BP-initiated tumorigenesis, compared with C57BL/6. C3H has the H-2k allele, C57BL/6 the H-2b allele; differences in these alleles have been found to be related to susceptibility to viral-induced tumors and perhaps immune competence as well. Peak G was associated, at least in part, with complexes involving BP 4,5-oxide, whereas the other eight peaks were associated predominantly with metabolites formed by cytochrome P₁-450 rather than other forms of P-450. Interestingly, in view of the CI's, no peak from C3H was greater than twice that of C57BL/6. (65 refs)

- 79-2069 Fluorescence Study of the Physico-chemical Properties of a Benzo(a)pyrene 7,8-Dihydrodiol 9,10-Oxide Derivative Bound Covalently to DNA.** (Eng) Prusik, T. (Chemistry Dept., New York Univ., New York, NY, 10003); Geacintov, N. E.; Tobiasz, C.; Ivanovic, V.; Weinstein, I. B. *Photochem Photobiol* 29(2): 223-232; 1979.

An in vitro system that mimics exactly the stereoselective in vivo binding of benzo(a)pyrene (BP) to DNA was developed. Using fluorescence lifetime and quenching studies, it was shown that the 7,8-dihydrodiol 9,10-oxide benzo(a)pyrene molecule bound to native DNA is definitely not intercalated in the DNA helix, in contrast to BP physically bound to DNA. (29 refs)

- 79-2070 Effect of *Nocardia Rubra* Cell-Wall Skeleton on the Induction of Lung Cancer in ACI/N Rats.** (Eng) Namba, M. (Third Dept. Internal Medicine, Osaka Univ. Medical Sch., Fukushima 1-1-50, Fukushima-ku, Osaka 553, Japan); Yoshimoto, T.; Ogura, T.; Hirao, F.; Azuma, I.; Yamamura, Y. *Gann* 70(1): 55-62; 1979.

The effect of oil-attached *Nocardia rubra* cell-wall skeletons (NR-CWS: 7 sc injections of 100 μ g given at 2-wk intervals) on the induction of lung tumors in ACI/N rats by benzo(a)pyrene (BP: 3 mg/wk given intratracheally for 15 wk) + ferric oxide (FO: 3 mg/wk given intratracheally for 15 wk) was determined. BP + FO induced primarily squamous cell carcinoma and squamous cell carcinoma + fibrosarcoma in 71.4% of the treated rats. Treatment with NR-CWS significantly reduced the lung tumor incidence in the BP + FO-treated rats to 48.0% and prolonged the latent period for tumor induction. The first tumor in the group treated with BP + FO appeared at 15 wk, whereas the first tumor in the group treated with BP + FO and NR-CWS did not appear until 31 wk. No fibrosarcomas were observed in the rats treated with BP + FO and NR-CWS. (28 refs)

79-2071 Neoplastic Effects of Oral Administration of (\pm)-trans-Dihydroxy-7,8-dihydrobenzo[a]pyrene and Their Inhibition by Butylated Hydroxyanisole. (Eng) Wattenberg, L. W. (Dept. Lab. Medicine and Pathology, Univ. Minnesota Medical Sch., Minneapolis, MN, 55455); Jerina, D. M.; Lam, L. K.; Yagi, H. *J. Natl Cancer Inst* 62(4): 1103-1106; 1979.

The neoplastic effects of administration of benzo[a]pyrene (BP) and (\pm)-trans-7,8-dihydroxy-7,8-dihydrobenzo[a]pyrene (BP 7,8-dihydrodiol) by oral intubation of noninbred female Ha:ICR mice have been determined. Under the experimental conditions, BP induced papillomas of the forestomach. BP 7,8-dihydrodiol also induced papillomas of the forestomach and was more potent than BP. In addition, administration of BP 7,8-dihydrodiol caused a large number of pulmonary adenomas and lymphomas. Butylated hydroxyanisole (BHA) added to the diet at a concentration of 5 mg/g inhibited BP-induced neoplasia of the forestomach. BHA also inhibited neoplasia of the forestomach, lungs, and lymphoid tissues that was caused by administration of BP 7,8-dihydrodiol. These data suggest that the inhibitory effect of BHA on BP carcinogenesis may entail events that occur subsequent to the formation of BP 7,8-dihydrodiol. (30 refs)

79-2072 Aryl Hydrocarbon Hydroxylase Activity in Mice Fed Benzo(a)pyrene and Varying in Source and Concentration of Protein (Meeting Abstract). (Eng) Truex, C. R. (Univ. Illinois, Urbana, IL, 61801); Clinton, S. K.; Visek, W. J. *Fed Proc* 38(3, part 1): 691; 1979. (1 ref)

79-2073 Aryl Hydrocarbon [Benzo(a)pyrene] Hydroxylase in Rat Mammary Tissue During Pregnancy and Lactation. (Eng) Fysh, J. M. (Dept. Biology, Univ. Windsor, Windsor, Ontario N9B 3P4, Canada); Okey, A. B. *Can J Physiol Pharmacol* 57(1): 112-117; 1979.

Aryl hydrocarbon hydroxylase (AHH) activity in microsomes from mammary tissue and liver was measured throughout the course of pregnancy and lactation in Sprague-Dawley rats to determine if altered capacity to metabolize polycyclic aromatic hydrocarbons (PAH's) could explain the resistance of rats to tumor induction during this period. Basal constitutive AHH activity in mammary tissue and liver of untreated rats did not change significantly during pregnancy or lactation. In rats injected with β -naphthoflavone (BNF: 80 mg/kg ip), AHH activity in liver microsomes increased 25-fold over basal levels and remained relatively constant throughout pregnancy and lactation. In mammary tissue, however, the induction of AHH by BNF increased from 12- to 86-fold when expressed per unit protein and from 19- to 106-fold when expressed per unit DNA. Since basal AHH and its inducibility in liver are not altered during pregnancy or lactation, it is

unlikely that changes in the hepatic metabolism of PAH's account for the great resistance of pregnant and lactating rats to PAH induction of mammary tumors. It is suggested that the local metabolism of PAH's by mammary tissue may be important in contributing to the resistance of these rats to tumor induction. The balance between local activation and detoxification of PAH's by AHH in mammary tissue during different physiological states is important in determining susceptibility to carcinogenesis. (13 refs)

79-2074 Antagonistic Action Between Cyclic Adenosine 3':5'-Monophosphate and Estrogen in Rat Mammary Tumor Growth Control. (Eng) Cho-Chung, Y. S. (Lab. Pathophysiology, NCI, NIH, Bethesda, MD, 20014). *Cancer Res* 38(11, part 2): 4071-4075; 1978.

Evidence that the regulation of hormone-dependent rat mammary tumor growth may depend on the antagonistic action between estrogen (E) and cyclic AMP (cAMP) was obtained by measuring (1) E- and cAMP-binding activities in biopsy specimens of 35 7,12-dimethylbenz(a)anthracene (DMBA)-induced or transplanted Sprague-Dawley rat mammary carcinomas and (2) the tumor responses to host ovariectomy (Ov-x). When hormone-dependent DMBA tumors underwent growth arrest following Ov-x or dibutyl cAMP (dbcAMP) treatment (10 mg/day, sc), the binding activities changed. Three days after either treatment, cAMP binding increased five- and twofold in the tumor nuclei and cytosols, respectively, but nuclear and cytoplasmic E binding decreased by 70% and 25%, respectively. These changes were detectable within 1 day, and they were reversed when tumor growth resumption was induced by injection of estradiol valerate or cessation of dbcAMP treatment. When the tumors failed to regress after either treatment, the change in both binding activities did not occur. Concomitant with the increase in cAMP binding in the regressing tumors was an increase in protein kinase activity and cAMP level. Further evidence of an interrelationship between cAMP and E at the nuclear level, both in vivo and in vitro, was shown by the stimulation and prevention of endogenous phosphorylation of nuclear proteins, identified as regression-associated proteins, by cAMP and E, respectively. The inverse relationship between cAMP and E binding was closely related to the hormone dependence of tumor growth. Thus, the integrity of both cAMP-binding proteins and E receptors is probably essential for the control of hormone-dependent mammary tumor growth. (30 refs)

79-2075 The Effects of Jejuno-Ileal Resection on Colonic Mucosal Cytochrome P450 (P450)-dependent Enzymes (Meeting Abstract). (Eng) Correia, M. A. (Univ. California, San Francisco, CA, 94143); Olson, S.; Deveney, C. *Fed Proc* 38(3, part 1): 692; 1979. (no refs)

- 79-2076 Rat Hepatic Nuclear Cytochrome P-450 and Epoxide Hydrase in Membranes Prepared by Two Methods: Similarities with the Microsomal Enzymes.** (Eng) Mukhtar, H. (Lab. Pharmacology, Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC, 27709); Elmamlouk, T. H.; Philpot, R. M.; Bend, J. R. *Mol Pharmacol* 15(1): 192-196; 1979.

DNase digestion and sucrose density centrifugation experiments showed that rat hepatic nuclear (Nu) and microsomal (Ms) cytochrome P-450 forms cannot be distinguished on the basis of their CO difference spectra and that the inductive effects of phenobarbital and 3-methylcholanthrene on Nu and Ms cytochrome P-450 and epoxide hydrase (EH) are similar. The similar characteristics of the hepatic Nu and Ms monooxygenase (MO) systems and EH suggest a common biogenesis. The presence of significant MO and EH activities in the nucleus is consistent with a role for this organelle in the bioactivation of environmental pollutants to carcinogens and/or mutagens. - 79-2079 Maturational Changes in Adrenal Xenobiotic Metabolism in Male and Female Guinea Pigs.** (Eng) Pitrolo, D. A. (Dept. Physiology and Biophysics, West Virginia Univ. Medical Center, Morgantown, W. Va., 26506); Rumbaugh, R. C.; Colby, H. D. *Drug Metab Dispos* 7(1): 52-56; 1979.

Changes in hepatic and adrenal enzyme activities with age and sex were studied in strain 2 guinea pigs. Hepatic microsomal protein and hepatic and adrenal cytochrome P-450 concentrations plus adrenal 21-hydroxylase activity did not vary with age or sex. Adrenal microsomal protein concentration, adrenal NADPH-cytochrome c reductase activity, and the rates of adrenal benzo(a)pyrene (BP) and ethylmorphine (EM) metabolism increased with age, but microsomal protein and NADPH-cytochrome c reductase did not vary with sex. BP and EM metabolism were significantly higher in males > 50 days of age than in females of the same age. Hepatic NADPH-cytochrome c reductase activity decreased with age, as did hepatic BP and EM metabolism; there were no

sex differences in these activities. Levels of microsomal protein and microsomal cytochrome P-450, NADPH-cytochrome c reductase activity, and BP and EM metabolism were greater in the adrenals than in the liver. The data suggest that opposite changes occur in adrenal and hepatic xenobiotic metabolism as a function of aging, resulting in substantially greater adrenal than hepatic activity in sexually mature animals, and that adrenal microsomal drug and steroid metabolism are independently regulated. - 79-2080 Lack of Inducibility of Lymphocyte Aryl Hydrocarbon Hydroxylase in Acute Leukemia of Childhood (Meeting Abstract).** (Eng) Blumer, J. L. (Case Western Reserve Univ., Cleveland, OH, 44106); Dunn, R.; Gross, S. *Fed Proc* 38(3, part 1): 658; 1979. (no refs)

- 79-2081 Aryl Hydrocarbon Hydroxylase in Cultured Lymphocytes of Twins.** (Eng) Paigen, B. (Dept. Molecular Biology, Roswell Park Memorial Inst., Buffalo, NY, 14263); Ward, E.; Steenland, K.; Houten, L.; Gurtoo, H. L.; Minowada, J. *Am J Hum Genet* 30(5): 561-571; 1978.

Aryl hydrocarbon hydroxylase (AHH) activity was measured in cultured lymphocytes of 18 monozygotic and 30 dizygotic twin pairs as part of a series of studies to determine whether there is a genetic polymorphism for AHH and whether the polymorphism affects cancer risk. Monozygotic twin pairs had strikingly similar basal and induced AHH activities and inducibility ratios (induced/basal). The data indicated that basal and induced AHH activity and AHH inducibility are heritable traits. Most of the dizygotic twins also had similar values, so that most of the variance used in determining heritability was contributed by only a few dizygotic pairs: 2 pairs contributed 61% of the variance for basal AHH, 4 contributed 70% for induced AHH, and 2 contributed 62% for AHH inducibility. The similarity of values for most dizygotic twins is consistent with the hypothesis that only one or a very few polymorphic genes determine AHH activities and inducibility. (29 refs)

- 79-2082 Aryl Hydrocarbon Hydroxylase Inducibility is not Altered in Bladder Cancer Patients or Their Progeny.** (Eng) Paigen, B. (Dept. Molecular Biology, Roswell Park Memorial Inst., Buffalo, NY, 14263); Ward, E.; Steenland, K.; Havens, M.; Sartori, P. *Int J Cancer* 23(3): 312-315; 1979.

To determine the possible influence of aryl hydrocarbon hydroxylase (AHH) on susceptibility to bladder cancer in humans, AHH inducibility was measured in the cultured lymphocytes of 16 apparently cancer-free patients who had undergone resection for bladder cancer, 53 progeny of bladder cancer patients, and matched controls. The progeny and

matched controls showed similar distributions of AHH inducibility except for a possible increase in the number of progeny at the high end of the AHH inducibility range. This apparent increase was not significant. There were no significant differences in AHH inducibility among progeny when those whose parents developed bladder cancer below 60 yr of age were compared with those whose parents developed bladder cancer after 60 yr of age, or when progeny with strong family histories of cancer were compared with controls with no family history of cancer. The basal and induced levels of AHH activity did not vary between progeny and controls, and the distribution of AHH activity was comparable for patients with bladder cancer and their matched controls. Thus, AHH activity of inducibility does not appear to be a major determinant of bladder cancer risk in humans. (24 refs)

79-2085 N-(4-Hydroxyphenyl)retinamide, a New Retinoid for Prevention of Breast Cancer in the Rat. (Eng) Moon, R. C. (IIT Res. Inst., Chicago, IL, 60616); Thompson, H. J.; Becci, P. J.; Grubbs, C. J.; Gander, R. J.; Newton, D. L.; Smith, J. M.; Phillips, S. L.; Henderson, W. R.; Mullen, L. T.; Brown, C. C.; Sporn, M. B. *Cancer Res* 39(4): 1339-1346; 1979.

A comparison was made of the toxicity and inhibition of breast cancer induction of N-(4-hydroxyphenyl)-all-trans-retinamide (HPR) and retinyl acetate (RA) in Sprague-Dawley rats. HPR was markedly less toxic than RA when given to rats over 2 wk (30.4 or 45.6 micromoles, 5x/wk po) or 6 mo (1 or 2 millimoles/kg of diet). HPR was an effective agent for the inhibition of breast cancer induction by N-nitroso-N-methylurea (15 or 50 mg/kg iv, 2x, 7 days apart) but it was not as potent as RA in this respect. High-pressure liquid chromatographic analyses of liver and breast extracts from rats treated with retinoids for 6 mo showed high concentrations of HPR and its metabolites in breast tissue without any measurable accumulation in the liver or evident liver toxicity. Chronic feeding of RA, however, caused marked deposition of retinyl esters in the liver and severe hepatotoxicity. Evaluation of whole mounts of mammary glands from rats treated with the

retinoids for 182 days showed that both RA and HPR had a marked antiproliferative effect on mammary epithelium. It is suggested that HPR, because of its lesser toxicity, is a superior agent for the prevention of breast cancer than RA. (22 refs)

79-2086 Effect of Time of Initiating Retinoid Treatment on the Inhibition of Urinary Bladder Carcinogenesis in the Rat (Meeting Abstract). (Eng) Becci, P. J. (IIT Res. 79-2088 Effect of Vitamin A Deficiency on Rat Hepatic and Colon Epoxide Hydrase. (Eng) Adekunle, A. A. (Biochemistry Dept., Univ. Ibadan, Ibadan, Nigeria); Campbell, T. C.; Campbell, S. C. *Experientia* 35(2): 241-242; 1979.

Metabolic studies of the conversion of 7-³H-styrene oxide to 7-³H-styrene glycol by epoxide hydrase were performed with liver microsomes and homogenized colon mucosal linings prepared from male weanling Sprague-Dawley-derived rats fed a corn-based diet without vitamin A or on a diet supplemented with 5 mg of vitamin A palmitate/kg diet for 45 days. The colon tissue of deficient animals exhibited a significantly higher (39%) value of V_{max} than the same tissue from supplemented animals. The liver tissue of deficient animals had a lower (8%) V_{max} value than the same tissue from supplemented animals. This implies that under vitamin A supplementation, free substrate would be available for complementation with RNA, DNA, and tissue protein but that the higher K_m value at which the reaction proceeds in vitamin A-supplemented animals may reduce such possibilities. The reverse of this interpretation as applied to vitamin A-deficient animals may explain carcinogenesis in these animals under drug metabolism. (26 refs)

79-2090 Development of DES-Associated Clear-Cell Carcinoma: The Importance of Regular Screen-

ing. (Eng) Anderson, B. (Dept. Obstetrics & Gynecology, New England Medical Center Hosp., 171 Harrison Ave., Boston, MA, 02111); Waring, W. G.; Edinger, D. D.; Small, E. C.; Netland, A. T.; Safaii, H. *Obstet Gynecol* 53(3): 293-299; 1979.

A case is presented that is believed to represent the first reported instance of clear cell adenocarcinoma of the vagina in a diethylstilbestrol (DES) exposed (in utero) woman who initially had negative examinations. The patient was first evaluated at age 15 yr and was followed with Papanicolaou smears, pelvic examinations, and colposcopy every 6 mo for 2 yr prior to discovery of the malignancy. Palpation aided by colposcopy allowed direct biopsy of the small asymptomatic lesion on the right posterolateral wall of the upper third of the vagina. Changes consistent with adenosis were observed in the upper anterior and posterior vaginal walls, but a transition from benign adenosis to adenocarcinoma was not demonstrated. The individual at high risk of development of adenocarcinoma is under the age of 24 yr and has symptoms of abnormal bleeding or discharge, or extensive columnar ectopy of the cervix or vagina. Frequent Papanicolaou vaginal smears and regular, careful palpation with biopsy of all suspicious cystic or nodular vaginal masses are minimum requirements for screening such patients. Colposcopy has also proved useful. (10 refs)

79-2091 Ultrastructure of Clear Cell Adenocarcinoma of the Vagina and Cervix in DES-exposed Progeny: Analysis of 16 Cases (Meeting Abstract). (Eng) Dickerson, G. R. (Massachusetts General Hosp., Boston, MA); Welch, W. R.; Erlandson, R. A.; Robboy, S. J. *Lab Invest* 40(2): 252; 1979. (no refs)

79-2092 Diethylstilbestrol-induced Upper Genital Tract Abnormalities. (Eng) Haney, A. F. (Div. Reproductive Endocrinology and Oncology, Duke Univ. Medical Center, Durham, NC, 27710); Hammond, C. B.; Soules, M. R.; Creasman, W. T. *Fertil Steril* 31(2): 142-146; 1979.

Hysterosalpingography was used to quantitate upper genital tract changes among 13 women who had been exposed to diethylstilbestrol (DES) in utero, and the results were compared with those obtained from 22 non-DES-exposed nulliparous women. Among the DES-exposed patients, 40% had frequent complaints of primary dysmenorrhea and 47% complained of irregular menses. All but one had upper genital tract abnormalities. There were no significant differences between the upper genital tracts of patients with only cervical changes as opposed to those with both cervical and vaginal changes. The upper uterine segment, endometrial cavity area, and widest diameter of the endocervical canal were significantly smaller in the DES-exposed women than in the controls. Marked irregularity of the endometrial contour was apparent in virtually every patient. The circumference of the

endometrial cavity did not differ significantly between DES-exposed women and controls. The results support the hypothesis that DES may affect the developing hypothalamic-pituitary axis, thereby disturbing the normal cyclic release of gonadotropin. (11 refs)

79-2093 Evolution of Diethylstilbestrol-associated Lower Genital Tract Abnormalities (Meeting Abstract). (Eng) Antonioli, D. A. (Beth Israel Hosp., Boston, MA, 02215); Burke, L.; Rosen, S. *Lab Invest* 40(2): 238; 1979. (no refs)

79-2094 Vaginal Epithelial Changes in Young Women Enrolled in the National Cooperative Diethylstilbestrol Adenosis (DESAD) Project. (Eng) O'Brien, P. C. (Mayo Clinic Coordinating Center, Rochester, MN); Noller, K. L.; Robboy, S. J.; Barnes, A. B.; Kaufman, R. H.; Tilley, B. C.; Townsend, D. E. *Obstet Gynecol* 53(3): 300-308; 1979.

Clinical findings at the time of initial examination in 3,339 women enrolled in the National Cooperative Diethylstilbestrol (DES) Adenosis project are reported. Eighty-eight percent of the enrollees had documented prenatal exposure to DES. Vaginal epithelial changes (VEC), which were detected by colposcopy or iodine staining, occurred in 34% of 1,275 participants identified by review of prenatal records, 59% of the participants who requested entry into the project, and 65% of the participants who were referred by a physician. VEC were most commonly observed on the anterior and posterior vaginal walls, with extension into the lateral fornices usually occurring close to the cervix. Intraepithelial neoplasia and cancer were rare. Offspring with VEC were generally exposed in utero to larger total doses of DES over longer periods of time and beginning at an earlier age in gestation than were offspring without such changes. The occurrence of VEC was primarily associated with exposure initiated during the first 18 wk of gestation, and the frequency of VEC appeared to diminish with age over 26 yr. The single best predictor of VEC was the derived variable 'day started times dose.' (22 refs)

79-2095 Pathologic Findings in Young Women Enrolled in the National Cooperative Diethylstilbestrol Adenosis (DESAD) Project. (Eng) Robboy, S. J. (Harvard Medical Sch. and Massachusetts General Hosp., Boston, MA); Kaufman, R. H.; Prat, J.; Welch, W. R.; Gaffey, T.; Scully, R. E.; Richart, R.; Fenoglio, C. M.; Virata, R.; Tilley, B. C. *Obstet Gynecol* 53(3): 309-317; 1979.

Pathology findings in 3,246 biopsy specimens obtained during the initial examinations of 3,339 women enrolled in the National Cooperative Diethylstilbestrol (DES) Adenosis project are reported. Eighty-eight percent of the enrollees had

documented prenatal exposure to DES. Vaginal epithelial changes (VEC) on colposcopic examination or after iodine staining were observed in 34% of the 1,275 participants who were identified by review of prenatal records and in 53% of all participants. Forty-five percent of the participants with VEC who underwent biopsy had adenosis. Tuboendometrial epithelial cells were found in 3% of the cervical specimens positive for ectropion, 20% of the specimens with adenosis from the upper third of the vagina, 31% of those from the middle third, and 100% of those from the lower third. Metaplastic squamous epithelium was encountered in almost all biopsy specimens in which squamous epithelium was present. A usually mild inflammatory infiltrate was present in 66% of the specimens. Squamous cell dysplasia was rare and was found in only 0.4% of the participants identified through review of prenatal records. Four cases of clear cell adenocarcinoma, all in the upper third of the vagina, were found. Although three of these patients had had Papanicolaou smears suggestive of squamous cell dysplasia in the past, the clear cell adenocarcinoma in two of them was discovered as a result of the present examination. The results indicate that the frequency of adenosis reflects that of VEC. (29 refs)

79-2096 Blockade by Vitamin A of the Occurrence of Permanent Vaginal Changes in Mice Treated Neonatally with 5 α -Dihydrotestosterone. (Eng) Iguchi, T. (Shigei Medical Res. Inst., Yamada, Okayama 701-02, Japan); Takasugi, N. *Anat Embryol (Berl)* 155(2): 127-134; 1979.

The effect of vitamin A (VA: 200 IU/day sc for 5 days beginning on day 0 or 5 after birth, or 400 IU/day sc for 5 days beginning on day 15 after birth) on the induction of permanent vaginal changes by 5 α -dihydrotestosterone (DHT, 50 μ g/day sc for 5 days beginning on day 0 after birth) was studied using female C57Black/Tw mice. The mice were ovariectomized on day 10 or 80 after birth. Estrogen-dependent persistent proliferation and cornification of the vaginal epithelium and permanent proliferation and squamous metaplasia of the uterine epithelium occurred in the ovariectomized adult mice treated with DHT. VA given with, but not after, DHT prevented the occurrence of permanent vaginal and uterine changes. In 45% of the mice given DHT + VA, clear cells with pale cytoplasm appeared in the basal layer of the degenerating epithelium. These cells appeared in only 13% of the mice given DHT alone. The results suggest that VA may prevent permanent vaginal and uterine changes induced by DHT only when given in combination with the androgen in neonatal life. (23 refs)

79-2097 Myeloproliferative Disorder and Hepatocellular Adenoma Following Androgen Treatment of a Patient with Aplastic Anemia. (Jpn) Tsunematsu, Y. (Div. Pediatric Hematology-Oncology, Natl. Children's Hosp., Tokyo, Japan); Sasaki, M.; Koide, R.; Shimizu, K. *Jpn J Clin Hematol* 19(12): 1699-1707; 1978.

The case of a boy with aplastic anemia who subsequently developed a myeloproliferative disorder and hepatocellular adenoma following androgen treatment is reported. After diagnosis of the aplastic anemia at age 6, the patient was treated with androgenic steroids (stanazolol, oxymetholone, testosterone enanthate, and ethynandiol) for 5.5 yr before he developed severe anemia and a mass in the left upper abdominal quadrant. A liver scan showed hepatomegaly with a large filling defect. Hepatitis B surface antigen and α_1 -fetoprotein were not detected; bone marrow examination showed normoblastic hyperplasia with numerous ringed sideroblasts. Chromosome examination revealed aneuploidy in 50% of the analyzed cells (44,X-Y, -21/45XY, -21/46XY 1q+). He died suddenly at age 15. Autopsy showed a well-differentiated hepatocellular adenoma, hypercellular marrow with myeloid cells, but no increase of atypical cells. The hepatocellular adenoma was concluded to have been induced by the long-term use of androgenic steroids. (21 refs)

79-2098 The Influence of Prenatal or Neonatal Administration of 2-Bromo- α -ergocryptine on Pituitary Prolactin Secretion and Normal and Neoplastic Mammary Growth in Adult Mice. (Eng) Nagasawa, H. (Pharmacology Div., Natl. Cancer Res. Inst., Tokyo, Japan); Yanai, R. *J Endocrinol Invest* 1: 273-276; 1978.

The effects of pre- or neonatal exposure to 2-bromo- α -ergocryptine (CB-154: 0.3 mg sc during gestation days 12-15 or 0.6 mg sc during postnatal days 1-5) on pituitary prolactin secretion and mammary tumorigenesis were studied in a strain of SHN mice with a high natural incidence of mammary tumors. Pre- or neonatal treatment with CB-154 had no significant effects on the estrus cycle; mammary gland development; histologic structure of the ovaries; wts of the anterior pituitary, ovaries, or adrenals; or pituitary or plasma prolactin levels. The first mammary tumor appeared at 5 mo in the control group, at 6 mo in the group treated prenatally, and at 7 mo in the group treated postnatally. The cumulative incidence of mammary tumors increased in all groups with age, but the incidence was significantly lower in the CB-154-treated animals than in the controls at 8 mo. The results indicate that pre- or neonatal exposure to CB-154 has little adverse effects on the pituitary-ovary-mammary gland systems at advanced ages. (20 refs)

79-2099 Longterm Effects of Neonatal Treatment with Cortisol and/or Estrogen in the Female BALB/c Mouse (40396). (Eng) Ways, S. C. (Dept. Zoology, Cancer Res. Lab., Univ. California, Berkeley, CA, 94720); Bern, H. A. *Proc Soc Exp Biol Med* 160(1): 94-98; 1979.

The long-term morphologic effects of neonatal cortisol (C) treatment (50 μ g/day sc for postnatal days 1 through 10), with and without subsequent estrogen (E) treatment to (20 μ g/day 17 β -estradiol ip for days 11 through 15), on the re-

productive and immune systems of female BALB/c mice were studied. Abnormal cycling (persistent diestrus or prolonged estrus) was significantly more frequent among animals given C + E or E alone than among controls. C alone was not related to abnormal cycling. The estrous cycle was eliminated by ovariectomy at 5 mo of age. The mean body wt of mice treated with C + E was significantly lower than the control value at 60 days and 6 mo; C alone was associated with a significant decrease in body wt at 60 days. Thymus wts on day 180 were significantly increased in intact animals treated with C, and adrenal wts were significantly decreased by ovariectomy. The spleen inguinal lymph node, and adrenal wts of the intact treated animals were not significantly different from those of controls at 6 mo of age. The uteri of all animals were normal. Ovaries lacking corpora lutea and containing hypertrophied interstitial cells were found in 77% of the animals given C + E and in 81% of those given E alone. The spleen, thymus, inguinal lymph nodes, and adrenals had a normal histology. (23 refs)

79-2100 Endometrial Findings in Postmenopausal Women Receiving Long-Term Estrogen Therapy.

(Eng) Dabancens, A. (Casilla 6606-Correo 7, Santiago, Chile); Fuensalida, S.; Gonzalez, O.; Zanartu, J. *Cancer* 43(2): 658-660; 1979.

A prospective morphological study of the endometrium was undertaken in 43 postmenopausal women who had been given conjugated estrogens on a cyclic schedule for an av of 7 yr, 8 mo. Duration of therapy was positively correlated with the age of the patient. Ten of the women had received 0.625 mg of estrogen daily and 33 had received 1.25 mg/day; the incidence of withdrawal uterine bleeding was lower in the lower dose group. Hyperplastic lesions were more frequent and neoplastic conditions less frequent in the estrogen-treated patients compared with control subjects never treated with estrogen. The mean age of occurrence of these conditions was similar in treated patients and controls. Hyperplastic lesions were more frequent in patients given 1.25 mg/day estrogen than in those given only 0.625 mg/day, and the number of lesions increased with duration of treatment. Fifty percent of the treated women who had abnormal bleeding showed hyperplastic endometrial pathology. It is suggested that estrogen be given in the lowest possible dose for the shortest period of time to women without clinical and basal histologic evidence of endometrial disease. (16 refs)

Hosp., Worcester, MA, 01510); Chen, P. S.; Janower, M. L.; Farmelant, M. H.; Howard, J. T.; McDermott, W. *Am J Roentgenol* 132(3): 452-454; 1979.

The case of a patient in whom regression of a benign, oral contraceptive-associated, hepatic tumor was documented by angiographic and isotopic follow-up is presented. The patient became symptomatic following minor abdominal trauma. She had taken a mestranol-containing oral contraceptive for 5 yr. A 6-cm hepatic cell mass with marked hematoma formation was resected from the left lobe, but a very vascular 16-cm, nonhemorrhagic, hyperplastic nodule remained in the right lobe. One year later, angiography demonstrated marked reduction in the size of this tumor with some residual neovascularity. (12 refs)

79-2102 Mutagenicity of Complex Mixtures from Drinking Water. (Eng) Loper, J. C. (Dept. Microbiology, Univ. Cincinnati Coll. Medicine, Cincinnati, OH, 45267); Lang, D. R.; Smith, C. C. *Water Chlorination* 2: 433-450; 1978.

Residual organics concentrated from drinking water samples from five cities (Miami, Florida; New Orleans, Louisiana; Ottumwa, Iowa; Philadelphia, Pennsylvania; and Seattle, Washington) were tested for mutagenesis in the Salmonella/microsome system and for their ability to transform mouse BALB/3T3 1-13 cells. Each sample was processed sequentially to produce the reverse osmosis concentrate-organic extract (ROC-OE) and an ethanol-soluble eluate obtained from a macroreticular resin XAD-2 column (XAD eluate). Mutagenicity was detected for ROC-OE's from each city, the patterns being relatively stable for samples taken at 2- to 3-mo intervals. The ROC-OE's showed city-specific patterns regarding relative mutagenicities for *S. typhimurium* strains TA98 and TA100, relative amount of mutagenicity per milligram of residue, and distribution of mutagenic activity after fractionation. Metabolic activation produced little or no enhancement of mutagenic activity. ROC-OE fractions were 10- to 20-fold more toxic than the corresponding XAD eluates. Comparison of the transforming ability of a New Orleans ROC-OE with that of the known carcinogen 3-methylcholanthrene showed that the ROC-OE caused higher transformation rates at concentrations of 10-100 µg/ml. (12 refs)

79-2101 Contraceptive-associated Hepatic Tumor. (Eng) Benedict, K. T. (Dept. Radiology, St. Vincent

79-2103 Residue Organic Mixtures from Drinking Water Show In Vitro Mutagenic and Transforming

Activity. (Eng) Loper, J. C. (Dept. Microbiology, Coll. Medicine, Univ. Cincinnati, Cincinnati, OH, 45267); Lang, D. R.; Schoeny, R. S.; Richmond, B. B.; Gallagher, P. M.; Smith, C. C. *J Toxicol Environ Health* 4(5/6): 919-938; 1978.

Residual organic samples were concentrated from drinking water from representative US cities by reverse osmosis followed by liquid-liquid extraction and sorption-desorption on resin. City-specific patterns of dose-dependent bacterial mutagenesis and of bacterial toxicity were observed for these samples and for subfractions generated by sequential extractions. Mutagenicity was essentially independent of microsomal activation. One fraction of a New Orleans sample transformed BALB/3T3 cells in replicate experiments. (23 refs)

PHYSICAL CARCINOGENESIS

- 79-2104 Action of DTPA on Hepatic Plutonium. II. DTPA-induced Removal of Monomeric Plutonium from Mouse Liver Parenchymal Cells.** (Eng) Bhattacharyya, M. H. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL, 60439); Peterson, D. P.; Lindenbaum, A. *Radiat Res* 76(1): 180-186; 1978.

The mechanism by which diethylenetriaminepentaacetic acid (DTPA) chelation therapy induces plutonium excretion was studied in mouse liver parenchymal cells. The cells were isolated following the administration of DTPA (0.25 millimoles/kg iv) to female CF-1 mice previously inoculated iv with ^{239}Pu citrate (4.4 $\mu\text{Ci/kg}$). The isolated parenchymal cells contained 440 disintegrations/min (dpm) Pu/ 10^6 cells 24 hr after Pu injection, just prior to DTPA administration. The Pu content decreased to 330 dpm/ 10^6 cells at 6 hr and 140 dpm/ 10^6 cells at 24 hr following DTPA injection. These decreases were not seen in Pu-treated controls that did not receive DTPA. The net DTPA-induced decrease in Pu concentration in the parenchymal cell portion of the liver was calculated to be 21,300 dpm/g, which corresponded well with the net decrease in Pu concentration for the whole liver (21,600 dpm/g). Liver parenchymal cells isolated 6 hr following DTPA administration and containing 330 dpm Pu/ 10^6 cells were incubated in vitro in the absence of added DTPA. After 18 hr of incubation, the cells contained 130 dpm Pu/ 10^6 cells. This level corresponded to the level observed in cells isolated 24 hr after DTPA injection. Cells isolated from untreated mice lost only 15% of their Pu content during a similar in vitro incubation. These studies suggest that, in the liver, DTPA acts preferentially on the Pu associated with parenchymal cells. Isolated liver parenchymal cells appear to retain their ability to release Pu in vitro 6 hr after DTPA administration with no need for additional DTPA exposure. (9 refs)

- 79-2105 Adoptive Transfer of Immune Deficits of ^{90}Sr -treated Mice with Spleen Cells (Meeting Abstract).** (Eng) Levy, E. M. (Boston Univ. Medical Center, Boston, MA, 02118); Bennett, M.; Kumar, V.; Fitzgerald, P.; Cooperband, S. R. *Fed Proc* 38(3, part 2): 1279; 1979. (no refs)

- 79-2106 Chromosome Aberrations as a Biological Dose-Response Indicator of Radiation Exposure in Uranium Miners.** (Eng) Brandom, W. F. (Dept. Biological Sciences, Univ. Denver, Denver, CO, 80210); Sac-

comanno, G.; Archer, V. E.; Archer, P. G.; Bloom, A. D. *Radiat Res* 76(1): 159-171; 1978.

Cultured peripheral blood lymphocytes of 80 uranium miners and 20 controls matched for age and smoking habits were examined for the prevalence of structural chromosomal aberrations. A sputum-cell cytology study was also carried out in 64 of the miners. The latter study revealed that the proportion of lymphocytes with any chromosomal aberration as well as the proportion with two-hit aberrations were higher in miners with a greater percentage of atypical cells than in those with normal or mildly to moderately aberrant cells ($p < 0.02$), even though the radiation exposure was comparable for the two groups. Study of the culture lymphocytes revealed no significant difference between miners and controls in the prevalence of dicentric + rings. When either the proportion of miners with aberrant cells or the proportion of miners' cells containing aberrations was compared with similar proportions in the controls, all other aberration categories were significantly higher among the miners ($p < 0.001$). There was a marked decrease in the prevalence of deletions or dicentric + rings + deletions in miners exposed to the highest levels of radiation. Apart from the results in this group, all aberration categories except dicentric + rings demonstrated a significant and monotonic biological response that increased uniformly with estimated radiation dose. The aberration category that showed the most consistent pattern of increase with dose was pericentric inversions + translocations. The results demonstrate that the prevalence of dicentric + rings is not a good biological dose-response indicator. However, the prevalence of chromosome aberrations other than dicentric + rings is a sensitive biological indicator of low-level uranium miner irradiation. (42 refs)

- 79-2107 Effects of a Single High Dose of ^{55}Fe in Mice.** (Eng) Laissue, J. A. (Inst. Pathology, Kantonsspital, CH-6004 Lucerne, Switzerland); Burlington, H.; Cronkite, E. P.; Heldman, B.; Reincke, U. *Virchows Arch [Cell Pathol]* 29(4): 321-335; 1979.

The effects of a single high dose of iron-55 (2,800, 1,400, or 700 μCi iv) on 10- to 14-wk-old female C57BL/6J mice were investigated. A corresponding amount of cold iron was given to control animals by the same route. Mice given 2,800 μCi of radioiron died after a median survival time of 27 days with severe depletion of hematopoietic cells in bone marrow and spleen. They also displayed marked atrophy of lymphoid tissues and mild liver damage. After 1,400 or 700 μCi , median survivals were 117 and 439 days, respectively, compared with

847 days in controls. A dose-dependent pancytopenia was noted in the two lower dose groups. Nodular regenerative-type hematopoiesis was occasionally noted in the spleen. Atrophy of lymphoid tissues was moderate, and signs of liver damage were slight. The degree of organ hemosiderosis in experimental and control animals was slight to moderate. Tumors of hematopoietic and lymphoid tissues or osteosarcomas were seen in 12/14 radioiron-treated mice who survived > 300 days. Only three reticulum cell neoplasms, which are common in this mouse strain, were noted in control mice (679-977 days after treatment). Since the presence of radioactivity was the only difference between experimental and control mice, it is concluded that the induction of neoplasms must be linked to the radioactive decay of ^{55}Fe . (36 refs)

79-2108 Relevance of Specific Activity in Experimental Erythrocytocide by ^{55}Fe . (Eng) Reincke, U. (Medical Res. Center, Brookhaven Natl. Lab., Upton, NY, 11973); Brookoff, D.; Cronkite, E. P.; Hillman, M.; Wilcox, D.; Burlington, H. *Experientia* 35(2): 277-280; 1979.

The relevance of specific activity in experimental ^{55}Fe erythrocytocide was studied in Swiss albino mice who were inoculated iv with 5 μCi ^{55}Fe in 0.2-10 μg total iron. ^{55}Fe was used instead of ^{59}Fe in this model experiment designed to illustrate and define the degree of competition between radioactive and stable iron. The influence of concomitant iron load on isotope uptake was plainly visible. Relative organ uptake increased as a function of iron load in the liver and kidneys but it decreased in the bone marrow and blood. With the passage of time, the remaining isotope in each organ converged toward a common value regardless of initial iron load. This occurred at different speeds in different tissues and required 7 wk in the blood, 9 wk in the hindlegs, and > 10 wk in the liver and kidneys. Whole body iron retention was not influenced by the injected iron load. Thus, the observed organ-specific differences were due to differences in initial iron distribution and not to differences in iron elimination via the kidney and intestines. The data reemphasize the relevance of specific activity for the organ distribution of injected radioiron. Most likely, competition between radioactive and stable iron at the transferrin binding site and at the site of the erythron determines the initial isotope uptake in bone marrow and blood. The present results show that ionic iron can be given iv in amounts far exceeding the free-iron-binding capacity of serum. Therefore, the relevance of specific activity does not so much concern the feasibility as it does the reproducibility of ^{55}Fe erythrocytocide. (17 refs)

79-2109 Mutagenesis in Yeast Cells by Storage in Tritiated Water. (Eng) Ito, T. (Inst. Physics, Coll. General Education, Univ. Tokyo, Meguroku Komaba 3-8-1, Tokyo 153, Japan); Kobayashi, K. *Radiat Res* 76(1): 139-144; 1978.

The mutagenic effects of tritiated water on *Saccharomyces cerevisiae* cells in suspension were studied by measuring mitotic gene conversion at *trp 5*. At both 31 and 62 mCi/ml $^3\text{H}_2\text{O}$, the frequency of revertants increased linearly with the time that the cells remained in suspension with $^3\text{H}_2\text{O}$. The frequency increase per unit treatment time indicated a significant dependence upon $^3\text{H}_2\text{O}$ concentration. Based on the calculated β -particle dose, the mutagenicity of $^3\text{H}_2\text{O}$ was two or three times higher than that produced by γ irradiation with ^{137}Cs . (10 refs)

79-2110 Acute Monocytic Leukemia in an Irradiated Beagle. (Eng) Tolle, D. V. (Div. Biological and Medical Res., Argonne Natl. Lab., 9700 S. Cass Ave., Argonne, IL, 60439); Seed, T. M.; Fritz, T. E.; Lombard, L. S.; Poole, C. M.; Norris, W. P. *Vet Pathol* 16(2): 243-254; 1979.

Acute monocytic leukemia was induced by chronic irradiation in a female Beagle dog, and the subsequent clinical course, hematology, necropsy findings, histological findings, and leukemic cell characteristics are described. The dog had received a total of 2,000 R of protracted whole-body γ -radiation from ^{60}Co over a 117-day period, beginning at the age of 14 mo. Three years following the termination of radiation exposure, the animal developed hematologic changes consistent with a myeloproliferative disorder. Peripheral blood and bone marrow findings during the 7-mo period before death showed progressive anemia with increased numbers of platelets, immature granulocytes, monocytes, and promonocytes. A period of partial remission occurred that lasted from days 113 to 59 before death. During this time the peripheral blood was aleukemic, although there was marked thrombocytosis and abnormal erythropoiesis that was evidenced by bizarre circulating nucleated RBC, anisocytosis, poikilocytosis, and Howell-Jolly bodies. The dog had a terminal crisis with marked leukocytosis; most of the peripheral blood cells were bizarre monocytes and promonocytes. At necropsy, diffuse and focal infiltration of the spleen, liver, lymph nodes, heart, kidney, and gastrointestinal wall with immature neoplastic cells resembling monocytes and monocytic precursors was observed. The monocytic differentiation of the invasive cell population was confirmed by morphological, cytochemical, histological, ultrastructural, and in vitro cell culture studies. (22 refs)

79-2111 Radiation-induced Chromosome Aberrations in Nuclear-Dockyard Workers. (Eng) Evans, H. J. (Medical Res. Council, Clinical and Population Cytogenetics Unit, Western General Hosp., Edinburgh, Scotland); Buckton, K. E.; Hamilton, G. E.; Carothers, A. *Nature* 277(5697): 531-534; 1979.

The incidence of chromosome aberrations in the peripheral blood lymphocytes of 197 dockyard workers was followed over a 10-yr period from 1968 to 1978. These workers were

exposed to mixed neutron- γ radiation during the refueling of nuclear reactors, but most exposures were below the internationally accepted max permissible level of 5 rem(roentgen-equivalent-man)/yr. The data showed a significant dose-dependent increase in chromosome aberrations in the peripheral blood WBC of the workers. There were no detectable second-order effects of dose, and all data were consistent with a linear dose response. Susceptibility to radiation-induced chromosome damage increased statistically with age, the trend being significant for dicentric aberrations. For all types of damage, the dependence on "recent" dose was greater than that on "early" dose, but the trend was not significant. There was no apparent increase in deaths attributed to or associated with leukemia in the area that included the dockyard during the period 1967 to 1977. (24 refs)

- 79-2112 Metastatic Cancer in Guinea Pigs Irradiated with Grenz Rays.** (Eng) Wulf, H. C. (Dept. Dermatology, Finsen Inst., 49 Strandboulevarden, DK-2100, Copenhagen O, Denmark); Hou-Jensen, K. *Arch Dermatol* 115(2): 176-178; 1979.

Four of 11 guinea pigs irradiated with 100, 200, or 300 rads of grenz rays (ie, long wavelength x-rays) four times weekly for 2 yr and observed for an additional 3 yr developed squamous cell carcinomas of the skin. All carcinomas occurred in animals that had received one of the two higher radiation doses. Three affected animals had regional lymph node metastases. Neoplastic cells showed the same degree of differentiation in the primary tumors as in the lymph nodes. (11 refs)

- 79-2113 Low-Level X-Radiation-induced Vascular Alterations in Normal and DMBA-treated, Tumor-bearing Cheek Pouch Epithelium of Syrian Hamsters.** (Eng) Lurie, A. G. (Univ. Connecticut Health Center, Farmington, CT, 06032); Rippey, R. M. *Radiat Res* 76(1): 127-138; 1978.

A study was made of late changes in vascular volume and perfusion of normal and tumor-bearing Syrian hamster cheek pouch epithelium initially treated with 7,12-dimethylbenz-(a)anthracene (DMBA) and/or repeated low-level x-radiation. The hamsters received a single 20-R head and neck irradiation per week for 17 wk. During weeks 1-5 and 7-11, 0.1% DMBA was applied topically to the right cheek pouches 2x/wk (24 hr before and after irradiation). All animals were sacrificed 39 wk after the first treatment. Functional hemodynamic studies were followed by histopathologic evaluations of all tissues. Hamsters treated with radiation only had no tumors, whereas 53% of the DMBA-treated animals had tumors and 75% of the animals treated with DMBA + radiation had tumors. Most of the excess tumor-bearing animals had extremely dysplastic papillomas that were considered to be premalignant lesions that eventu-

ally become invasive carcinomas. Irradiated cheek pouches had increased blood volume, and DMBA-treated tumor-bearing pouches had increased blood volume and perfusion. DMBA + radiation-treated tumor-bearing pouches had increased blood volume similar to that seen in irradiated pouches and increased blood perfusion similar to that seen in DMBA-treated, tumor-bearing pouches. Although the presence of DMBA-induced tumors was related to changes in vascular perfusion in all groups, low-level x-radiation appeared to alter changes in blood volume caused by DMBA or DMBA-induced tumors. (34 refs)

- 79-2114 Radiation-induced Cancer of the Esophagus after Postoperative Irradiation for Breast Cancer.** (Jpn) Ito, I. (Dept. Radiology, Gunma Univ. Sch. Medicine, Maebashi, Japan); Miyaishi, K.; Mitsuhashi, N.; Ito, J.; Inoue, T.; Niibe, H. *Nippon Acta Radiol* 38(10): 985-991; 1978.

Two cases of radiation-induced esophageal cancer after postoperative irradiation for breast cancer are reported. The latent periods were 12 and 16 yr and the radiation doses were 4,180 and 1,860 rads, respectively. The breast cancers were papillotubular carcinomas, and the esophageal cancers were a poorly differentiated and a moderately differentiated squamous cell carcinoma. Both esophageal lesions were serrated. (24 refs)

- 79-2115 Postirradiation Mixed Mullerian Tumors of the Uterus: A Comparative Clinicopathological Study (Meeting Abstract).** (Eng) Varela-Duran, J. (Dept. Pathology, Univ. Minnesota Medical Sch., Minneapolis, MN, 55455); Nochomovitz, E.; Dehner, L. P. *Lab Invest* 40(2): 290-291; 1979. (1 ref)

- 79-2116 Postirradiation Sarcoma of Bone: A Perspective.** (Eng) Tountas, A. A. (Dept. Pathology, Princess Margaret Hosp., 500 Sherbourne St., Toronto, Ontario, Canada M4X 1K9); Fornasier, V. L.; Harwood, A. R.; Leung, P. M. *Cancer* 43(1): 182-187; 1979.

The literature on postirradiation sarcoma of bone is reviewed, and 10 cases that were seen in a 20-yr period at one hospital are reported. In each of the 10 cases, the postirradiation sarcoma arose in previously healthy bone that had been included in the radiation field. Histologically, 6 were osteosarcomas, 1 was a chondrosarcoma, 2 were fibrosarcomas, and 1 was a sarcoma that was completely undifferentiated. The postirradiation sarcomas were particularly aggressive, with most of the patients having extensive metastases. By the time of diagnosis, none of the 10 cases was amenable to curative surgical resection. The overall incidence was calculated as 0.035% of all irradiated 5-yr survivors. When these data were combined with those of three other large series presented in

the literature, a dose-incidence curve could be deduced. On the basis of the human and animal data reviewed, it is concluded that the risk of radiation-induced sarcoma (0.05%-0.2%) is so low in the dose range of modern radiotherapeutic practice (4,000-7,000 rads) that it does not represent a contra-indication to the use of radiation therapy. (40 refs)

- 79-2117 An Atomic Bomb Survivor with Multiple Myeloma Accompanied by Basal Cell Carcinoma and Rectal Adenocarcinoma.** (Jpn) Yamaguchi, H. (Dept. Internal Medicine, Japanese Red Cross Society, Nagasaki Atomic Bomb Hosp., Nagasaki, Japan); Uchiyama, E.; Toyota, S.; Sugihara, H.; Takahara, O. *Jpn J Clin Hematol* 19(11): 1545-1550; 1978.

The case report of a Japanese atomic bomb survivor with multiple myeloma (IgG, heavy chain-type), basal cell carcinoma, and rectal adenocarcinoma is presented. The patient, a 46-yr-old woman, was 2 km from the epicenter at the time of the blast; therefore, the radiation level to which she was exposed was too low to cause the myeloma. Immunological studies revealed that she had a lowered cell-mediated immunity: negative purified protein derivative of tuberculin reaction, 37.5% T-cell lymphocyte level, and 45% lymphocytic transformation with phytohemagglutinin. Prednisolone (PN: 40 mg/day) and melphalan (2 mg/day) were administered daily until a basal carcinoma was discovered 9 mo later. After resection of this tumor, the dose of PN was lowered to 5-10 mg/day. The total duration of chemotherapy was 77 wk. Ten months later, the patient was found to have a rectal adenocarcinoma. Suppression of the immunological surveillance system associated with the myeloma is thought to be the cause of the multiple tumors in this patient. (13 refs)

- 79-2118 Solar Cycles and Malignant Melanoma.** (Eng) Viola, M. V. (Dept. Medicine, Univ. Connecticut Health Center, Farmington, CT, 06032); Houghton, A.; Munster, E. W. *Med Hypotheses* 5(1): 153-160; 1979.

A hypothesis is offered to explain the recent observation that the incidence of melanoma in Connecticut increases following max sunspot activity. It is proposed that sunspot cycles modulate the amount of stratospheric ozone and thus, indirectly, the amount of UV-B (290-320 nanometers) flux at the earth's surface. In both animal test systems and in human epidemiological studies, UV-B has been implicated as the major cause of skin cancer, including melanoma. A peak of sunspot activity occurred in 1957. According to data from the Connecticut Tumor Registry, there was a 22.2% increase in 1959 and a 10.5% increase in 1960 in incidence rates of melanoma above that anticipated by a linear regression equation relating melanoma incidence to time. Ozone variation was only 1%-2% decreased preceding this incidence rise. The increase in melanoma incidence related to a given reduction

in ozone depletion in this hypothesis is in great excess of that predicted by existing models relating anthropogenic ozone depletion and skin cancer. (27 refs)

- 79-2119 Bowen's Disease and Squamous Cell Carcinoma. Occurrence in a Patient with Psoriasis after Topical, Systemic, and PUVA Therapy.** (Eng) Tam, D. W. (Skin and Cancer Hosp., 3322 N. Broad St., Philadelphia, PA, 19140); Van Scott, E. J.; Urbach, F. *Arch Dermatol* 115(2): 203-204; 1979.

Multiple lesions of Bowen's disease and squamous cell carcinoma developed on the penis and pubic areas of a dark-complexioned, circumcised, 32-yr-old man with psoriasis who was undergoing treatment with psoralen and long-wave UV radiation (PUVA). A cumulative dose of >3,700 joules/cm² of UV radiation had been administered over a 3-yr period, a dose higher than that received by most PUVA patients. The cancerous lesions erupted precipitously in sites not normally prone to skin cancer. There was no known exposure to arsenic or ionizing radiation to the genitalia. In light of the possible association of cutaneous neoplasia with PUVA in this case, it seems advisable to use PUVA therapy as conservatively as possible in highly selected patients and that such patients be monitored closely after treatment. (6 refs)

- 79-2120 Development of Acute Myeloid Leukaemia in a Patient with Psoriasis Treated with Oral 8-Methoxypsoralen and Longwave Ultraviolet Light.** (Eng) Hansen, N. E. (Section Haematology, Dept. Medicine, Hvidovre Hosp., Kettegards Alle, DK-2650 Hvidovre, Denmark). *Scand J Haematol* 22(1): 57-60; 1979.

The development of acute myeloid leukemia in a 68-yr-old woman treated with 8-methoxypsoralen and long-wave UV light (PUVA) for psoriasis is reported. The PUVA treatment was administered for 11 mo, and it was terminated 2 yr before the patient was hospitalized with leukemia. When activated by UV light, 8-methoxypsoralen reacts with pyrimidine bases in opposite strands of the DNA duplex, thus cross-linking the DNA molecule. There is substantial evidence that PUVA induces profound changes on the molecular, chromosomal, and cellular levels and that it may induce cancer. It is quite possible that PUVA may induce changes in the hematopoietic system. Since the present case is the second reported occurrence of hematological disease in a PUVA-treated patient, a close and comprehensive follow-up of PUVA-treated patients is warranted. (16 refs)

- 79-2121 Toxicological Assessment of Potential Hazards from New Inorganic Fibers.** (Eng) Pigott, G. H. (Central Toxicology Lab., Imperial Chemical Industries Ltd., Alderley Park, Nr Macclesfield, Cheshire SK10 4TJ, En-

gland); Ishmael, J. *J Soc Occup Med* 29(1): 20-21; 1979.

An experimental program for evaluating the potential health hazards associated with inorganic fibers is discussed. To assess the hazards associated with a new fiber, lesions identical or very similar to those in humans are produced in rats. The potential hazard from inhalation of fibers is dependent on particle size, as only fibers with diameters less than 3-3.5 μm are respirable. A macrophage cytotoxicity test followed by ip or intratracheal injections of fiber suspensions into rats are used to test for fibrogenic potential. A severe test for potential mesothelioma production involves the single intrapleural injection of a large amount (20 mg) of fiber. This test, which is sensitive and gives clear cut results, showed no potential for mesothelioma production associated with alumina fiber, but a 15% rate of mesothelioma production with chrysotile asbestos. Both fibrosis and carcinogenesis can be assessed by inhalation experiments. The hazards of fiber ingestion are assessed by long-term feeding studies for chronic toxicity and carcinogenicity. 79-2122 The Induction of Rat Splenic Lymphocyte Blastogenesis by Alveolar Macrophages Following Chronic Asbestos Inhalation (Meeting Abstract). (Eng) Kagan, E. (Georgetown Univ. Medical Center, Washington, DC, 20007); Miller, K. *Fed Proc* 38(3, part 2): 1204; 1979. (no refs)

79-2123 Surface Charge in Foreign Body Carcinogenesis. (Eng) Andrews, E. J. (ETHICON Res. Foundation, Somerville, NJ, 08876); Todd, P. W.; Kukulinsky, N. E. *J Biomed Mater Res* 13(2): 173-187; 1979.

The importance of surface charge in foreign body carcinogenesis was evaluated by implanting bipolar polystyrene thermoelectrets formed in variously charged electrical fields (500-3,125 volts/cm) into male C3H/HeJ mice. Mice implanted with charged electrets had tumor rates similar to those in control groups. The combined data for mice with charged implants showed a tumor rate of 26.9%, compared with 17% for mice bearing electrets that were not exposed to an electric field (V-0 group) and 6% for mice bearing electrets that were exposed to 3,125 volts/cm (V-3125 group) and then rubbed with sterile sandpaper until no smooth surface remained. These data, however, were not statistically significant. Differences in tumor rates among the charged electret groups were minor except for the V-2000 group, which had a rate of 15.79%, lower than the V-0 control. These results suggest that neither the presence nor the intensity of the charge had any effect on tumorigenesis. The cumulative probabilities of tumor development as a function of time were calculated by actuarial techniques. The combined electret group had a higher probability, culminating at 0.58 at 133 wk when the study was terminated. The highest probability achieved by the V-0 control group was 0.17 at 117

wk. Although statistically significant differences in tumor rates could not be demonstrated at the 5% level, a definite trend toward increased tumor incidence existed in mice having charged electrets. The latent period of tumor induction varied little between groups and averaged approx 700 days. No conclusions regarding the tumorigenic effect of electropositive vs electronegative sides of the electret were made, although most tumors arose on the electronegative (body) side of the electrets. An occasional tumor (2/25) arose on both sides of a single electret. The antigenicities of tumors tested by excise and challenge techniques were weak. The immunologic relationship between top- and bottom-growing tumors on a single electret could not be determined adequately because of the weak antigenicity. (55 refs)

79-2124 Biologic Determinants of Tumor Growth in Healing Wounds. (Eng) Pendergrast, W. J. (Dept. Surgery, Emory Univ. Sch. Medicine, Atlanta, GA); Futrell, J. W. *Ann Surg* 189(2): 181-188; 1979.

The growth of an id transplanted methylcholanthrene (MCA)-induced liposarcoma (MCA-2) in surgical scars and healing operative wounds was studied in adult female Sewall-Wright strain-2 guinea pigs. Inoculation of tumor cells into 3-, 9-, or 11-wk-old scars resulted in tumor incidences of 78%, 50%, and 85%, respectively, whereas inoculation into acute wounds resulted in only a 20% tumor incidence. The tumor growth rate was also enhanced by inoculation of tumor cells into scar tissue. When wounds were made 1 wk after MCA-2 inoculation, the latency period between tumor injection and the appearance of palpable tumor was not decreased, but the subsequent rate of tumor growth around the wounds was significantly greater than the tumor growth rate in unwounded control animals. The results support the hypothesis that the relative paucity of lymphatic channel regeneration within scar tissue can render it a potential "immunologically privileged site," such that early recognition and destruction of tumor cells within the scar may be delayed long enough for the tumor to grow to a "critical size." VIRAL CARCINOGENESIS

79-2125 Persistence of Avian Oncoviruses in Chicken Macrophages. (Eng) Gazzolo, L. (Unite de Virologie, Place Joseph Renaut, 69008 Lyon, France); Moscovici, C.; Moscovici, M. G. *Infect Immun* 23(2): 294-297; 1979.

The presence of avian oncoviruses in plasma and macrophages (MP) from chickens infected with sarcoma or leukosis viruses was examined. In chickens infected with two avian leukosis viruses, myeloblastosis-associated virus (MAV-2) or Carr Zilber-associated virus (CZAV), infectious virus was found only in MP obtained from the peripheral blood 6-31 mo after viral infection. Neutralizing antibodies were always present in the sera of all chickens. In chickens infected with the Prague strain of Rous sarcoma virus subgroup A (PR-RSV-A) or avian sarcoma virus B77, no virus was detected in plasma or MP obtained 2-24 mo after infection either from chickens bearing a tumor or from chickens after tumor regression. The search for virus was also negative in cocultivation experiments using mixed cultures of MP and fibroblasts. Neutralizing antibodies were not detected in the sera obtained from birds infected with PR-RSV-A. MAV-2 was detected in spleen and bursa cells as well as in MP 1 mo after injection, but the percentage of MAV-2-positive spleen or bursa cells was 100- to 400-fold lower than that of MAV-2-positive MP. No sarcoma virus was detected in cells or in the plasma, confirming the previous results. The persistence of avian leukosis viruses in MP may be of significance when it is related to the long latent period preceeding the expression of oncogenic disease in animals inoculated with these viruses. (17 refs)

79-2126 Reverse Transcriptase from Avian Myeloblastosis Virus. (Eng) Houts, G. E. (Life Sciences, Inc., St. Petersburg, FL, 33707); Miyagi, M.; Ellis, C.; Beard, D.; Beard, J. W. *J Virol* 29(2): 517-522; 1979.

A comparatively simple, two-step chromatographic procedure that affords high yields of RNA-dependent DNA polymerase (RDDP, reverse transcriptase) from large amounts of avian myeloblastosis virus (AMV) is described. RDDP of >95% purity was obtained from 20- to 30-g lots of AMV by a two-step column chromatographic procedure employing diethylaminoethylcellulose and carboxymethylcellulose. Yields of RDDP varied from approx 20,000 to 35,000 units/g of virus. The specific activity of the enzyme was about 35,000-60,000 units/mg of protein. Free of detectable RNase activity, the product exhibited a mol wt of about 160,000 and an isoelectric point of 6.5, and it contained approx 2 moles of fatty acid per mole of enzyme. (22 refs)

79-2127 In Vitro Transformation of Hematopoietic Cells by Avian Erythroid and Myeloid Leukemia Viruses: A Model System for the Differentiation of Normal and Neoplastic Cells. (Eng) Graf, T. (Max-Planck-Institut fur Virusforschung, Biologisch-Medizinische Abteilung, D-7400 Tubingen, W. Germany); Beug, H.; Royer-Pokora, B.; Meyer-Glauner, W. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 625-639; 1978.

The in vitro transformation of hematopoietic cells by avian erythroid (AEV) and myeloid leukemia viruses (AMV and MC29) was studied. Chicken bone marrow cells infected with AEV, MC29, or AMV produced transformed foci as early as 3-4 days after infection. In their staining properties, the AEV- and AMV-transformed bone marrow cells resembled erythroblasts and myeloblasts, respectively, but the cells transformed by MC29 resembled macrophages. The erythroid markers Hb, histone H5, and chicken RBC surface antigen were detected in bone marrow cells transformed by AEV but not by MC29 or AMV. MC29-transformed bone marrow cells and, to a lesser extent, AMV-transformed cells were phagocytic. Both MC29- and AMV-transformed cells gave a specific fluorescence with serum prepared against cultured chicken macrophages and both possessed Fc receptors, whereas cells transformed by AEV were not phagocytic, did not stain with antimacrophage serum, and did not contain detectable Fc receptors. The target cells for AEV and the myeloid viruses could be separated. It is suggested that the target cells for MC29 and AMV belong to the myeloid lineage of differentiation and that the target cells for AEV belong to the erythroid lineage. AEV-transformed erythroblasts were inducible by butyric acid but not by dimethyl sulfoxide. These studies indicate that the erythroid and myeloid viruses do not affect a common population of stem cells, thus, that the differentiation stage of the target cells reflects the differentiation stage of the transformed cells. (17 refs)

79-2128 Tumor Specificity of Acute Avian Leukemia Viruses Reflected by Their Transformation Target Cell Specificity In Vitro. (Eng) Graf, T. (Biol.-Med. Abteilung, Max-Planck-Institut fur Virusforschung, D-7400 Tubingen, W. Germany); Royer-Pokora, B.; Meyer-Glauner, W.; Beug, H. *Med Microbiol Immunol (Berl)* 164(1/3): 139-153; 1977.

The results of current and previous studies concerning the tumor specificity of five transforming avian leukemia viruses are presented. These viruses included two erythroblastosis viruses [avian erythroblastosis virus (AEV) strain R and AEV strain ES] and three myeloid leukemia viruses [avian

myeloblastosis virus (AMV), avian myelocytomatosis virus strain MC29, and avian myelocytomatosis virus strain CMII]. Myeloid leukemia virus-transformed hematopoietic cells phagocytize fixed bacteria and latex beads, but AEV-transformed cells do not. Myeloid cells are dependent upon colony-stimulating factor for colony formation, but AEV cells are either weakly dependent or not dependent on this factor for colony formation. All three myeloid strains, but none of the erythroid strains, transform macrophage cultures, supporting the assumption that myeloid cells (macrophages) but not erythroid cells are the target cells for transformation by avian myeloid leukemia viruses. Both AEV strains are capable of transforming fibroblasts in vitro. Unlike AEV-transformed fibroblasts, MC29-transformed cells do not show an increased rate of deoxyglucose uptake. MC29-transformed chicken embryo fibroblasts and normal control cells possess similar amounts of large, external, transformation-sensitive (LETS) protein, but this protein is lost from AEV-transformed cells and Rous sarcoma virus-transformed cells. Although previous studies have demonstrated the sarcomagenicity of AEV-transformed fibroblasts, current attempts to induce solid tumors with MC29-transformed fibroblasts failed. The findings presented indicate that transforming avian leukemia viruses possess a high degree of in vitro target cell specificity in the hematopoietic system, reflecting the tumor spectrum obtained with the corresponding strains. - 79-2129 Structural Analysis of the Avian Sarcoma Virus Transforming Protein: Sites of Phosphorylation.** (Eng) Collett, M. S. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO, 80262); Erikson, E.; Erikson, R. L. *J Virol* 29(2): 770-781; 1979.

The polypeptide product of the avian sarcoma virus (ASV) transforming (*src*) gene is a 60,000-dalton phosphoprotein designated pp60*src*. The sites of phosphorylation on the pp60 *src* molecule were characterized in an effort to understand the functional regulation in cells of the ASV transforming protein. The technique of limited proteolysis during reelectrophoresis showed that pp60*src* contains two major sites of phosphorylation, one involving phosphoserine and the other involving phosphothreonine, and possible additional minor sites of phosphorylation. By using N-formyl[³⁵S]methionyl-transfer RNA-f as a radiolabeled precursor in the cell-free synthesis of the *src* protein in conjunction with partial proteolysis mapping, the phosphoserine residue was found to be located on the amino-terminal two-thirds of the molecule, the phosphothreonine residue on the carboxy-terminal third. The phosphorylation of pp60*src* in cell extracts involved at least two protein kinases: the one that phosphorylated the major serine site was cyclic AMP-dependent and the other, acting on the threonine residue, was a cyclic nucleotide-independent phosphotransferase. Finally, analysis of the pp60*src* isolated from cells infected with a temperature-sensitive *src* gene mutant of ASV revealed that phosphorylation of the major threonine residue was severely reduced

when infected cells were grown at the nonpermissive temperature, whereas a phosphorylation pattern characteristic of wild-type pp60*src* was observed at the permissive temperature. As pp60*src* has an associated protein kinase activity, phosphorylation-dephosphorylation reactions may possibly be involved in the functional regulation of ASV-transforming-protein enzymatic activity. - 79-2130 Description of Cell Populations Isolated In Vitro from LEW/CUB Rat Embryos.** (Eng) Vesely, P. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, Prague, Czechoslovakia); Kren, V.; Wyke, J.; Plaisner, V.; Sladka, M. *Folia Biol (Praha)* 24(6): 391; 1978.

The use of embryonic cells from highly inbred LEW/CUB rats for in vitro studies of neoplastic transformation by avian sarcoma viruses was investigated. Hepatocytes and epidermal cells were not cultured successfully, but no spontaneous transformation occurred in cultures of mixed embryo fibroblasts or kidney cells. The kidney cells were also negative for tumorigenicity in vivo, indicating the absence of an endogenous C-type virus in this strain or its resistance to induction. The genetic stability of LEW/CUB cells in vitro demonstrates that they are suitable for in vitro viral transformation studies. (1 ref)

- 79-2131 Effect of 5-Methylcytidine on Virus Production in Avian Sarcoma Virus-infected Chicken Embryo Cells.** (Eng) Guntaka, R. V. (Dept. Microbiology, Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032); Katz, R. A.; Weiner, A. J.; Widman, M. M. *J Virol* 29(2): 475-482; 1979.

As part of a series of experiments designed to study the role of modified nucleosides in the transcription and processing of RNA, the effect of 5-methylcytidine (5mC), a minor constituent of RNA in procaryotes as well as eucaryotes, on virus production in avian sarcoma virus-infected chicken embryo fibroblasts was determined. Surprisingly, virus release into the medium was severely reduced in cultures treated with 5mC. In contrast to the effect of 5mC on virus release, intracellular levels of virus-specific RNA transcripts and protein levels were slightly elevated. Thus, substitution of methylcytidine monophosphate for cytidine monophosphate in viral RNA suppresses virus production while allowing normal levels of transcription and translation of viral RNA. Analysis of intracellular RNA transcripts on velocity gradients and virus-specific proteins in polyacrylamide gels did not reveal any qualitative differences between 5mC-treated and cytidine-treated cells. It is concluded that the effect of 5mC is probably at the level of virus maturation or packaging. (22 refs)

79-2132 *src* Gene Product from Different Strains of Avian Sarcoma Virus: Kinetics and Possible Mechanism of Heat Inactivation of Protein Kinase Activity from Cells Infected by Transformation-defective, Temperature-sensitive Mutant and Wild-Type Virus. (Eng) Rubsamen, H. (Institut für Virologie, Fachbereich Humanmedizin, Justus-Liebig-Universität Giessen, Frankfurter Strasse 107, 63 Giessen, W. Germany); Friis, R. R.; Bauer, H. *Proc Natl Acad Sci USA* 76(2): 967-971; 1979.

Sera from rabbits bearing Schmidt-Ruppin strain Rous sarcoma virus (RSV)-induced tumors precipitated a 60,000-dalton transformation-specific phosphoprotein (p60src) from chicken cells transformed by the homologous virus as well as by other strains [Prague strain RSV, Bryan high-titer strain RSV, and the Bratislava 77 strain of avian sarcoma virus (ASV)]. The mol wts ranged from 60,000 to 64,000. The p60src immunoprecipitated from cells transformed by each of these strains incorporated [γ - 32 P]ATP into the 53,000-dalton subunit of IgG, although with differing protein kinase activities. No protein kinase activity (ATP:protein phosphotransferase) was observed when immunoprecipitates from uninfected cells, untransformed cells infected by Rous-associated virus, or cells transformed by acute leukemia viruses, avian erythroblastosis virus, or myelocytoma virus 29 were used. The kinase reaction had a pH optimum at 5.9 and an apparent K_m for ATP of 4.9 μ M, and it was dependent on Mg^{2+} . Ca^{2+} could not be substituted for the latter. The kinase was cyclic AMP-independent. In order to test whether the protein kinase reaction is directly catalyzed by p60src, the in vitro temperature sensitivities of the kinase activities from cells infected by a transformation-defective, temperature-sensitive mutant and parental wild-type virus were compared. The first-order rate constant for inactivation of the kinase from extracts of cells infected by the mutant virus was two-fold greater than that from cells infected by wild-type virus. This result implicates protein kinase as an enzymatic activity of p60src. Concomitant with the loss of kinase activity by heat inactivation, p60src loses 60%-70% of its phosphate content. The kinetics of dephosphorylation parallel those for inactivation of the kinase activity, suggesting that the p60src kinase is itself dependent on phosphorylation for its activity. (19 refs)

79-2133 Alterations in Surface Proteins of Rat Cells Transformed by Avian Sarcoma Virus B77. (Eng) Chorvath, B. (Cancer Res. Inst., Slovak Acad. Sci., 880 32 Bratislava, Czechoslovakia); Duraj, J.; Hlubinova, K.; Valentova, N.; Simkovic, D. *Neoplasma* 25(5): 541-548; 1978.

The cell-surface proteins of uninfected rat embryo fibroblasts and cells transformed by the Bratislava 77 (B77) strain of avian sarcoma virus were analyzed by sodium dodecyl sulfate-acrylamide gel electrophoresis. Compared with the uninfected cells, the virus-infected cells showed: a slight decrease in the levels of two high-mol-wt proteins [one presumably corresponding to the LETS (large, external, transforma-

tion-sensitive protein)]; a decrease in a protein of approx 50,000 mol wt; increases in proteins with mol wts of approx 70,000-75,000 and 90,000-95,000; and a marked increase in a protein with a mol wt of 30,000-35,000. There were no major differences in the quantities of these proteins in two different virus-infected cell lines (LWF B77 and LWF B55) or between monolayer and spinner cell cultures. Metabolic labeling of the plasma membrane proteins confirmed the results obtained with electrophoresis, and metabolic labeling of the cell membrane proteins indicated that the proteins of mol wt 70,000-75,000 and 90,000-95,000 were glycoproteins. (19 refs)

79-2134 Change of Isozyme Pattern During Activation of a Transforming Gene Product. Its Relation to Other Biochemical Markers of Cellular Transformation and Differentiation. (Eng) Roth, S. L. (Univ. Pennsylvania Sch. Medicine, Philadelphia, PA, 19104); Kaji, A. *Biochim Biophys Acta* 583(2): 241-252; 1979.

Isozyme patterns of leucine aminotransferase (LAT) were studied in connection with glucose transport and DNA synthesis during the activation and deactivation of the transforming gene product in rat kidney cells transformed by a Rous sarcoma virus with a temperature-sensitive lesion in its transforming gene. On temperature shift-down of confluent transformed cells grown at 40 C in the presence of fresh serum, isozyme III of LAT appeared within 12-20 hr and increased from 24 to 48 hr. Upon temperature shift-up, isozyme I became the predominant form in 4 days, the major change occurring within the first 24 hr. Isozyme I was more characteristic of sparse cultures, whereas isozyme III was predominant in denser cultures. The rate of protein turnover was similar to the rate of loss of isozymes I and III during temperature shift-down and shift-up, respectively. The transformed cells were stimulated to synthesize DNA 8-12 hr after shift-down from 40 C. Once this induction of DNA synthesis had taken place, return of the cells to 40 C did not completely abolish the induced DNA synthesis for at least 16 hr. The LAT isozyme pattern reflected the state of differentiation of the cells, with isozyme I being more characteristic of the myotubes and isozyme III being more predominant in the undifferentiated cells. (31 refs)

79-2135 Effect of Hormones on the Activation and Accumulation of Oncornavirus in Cell Cultures. (Rus) Kuznetsov, O. K. (Lab. Biochemistry, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Gaber, V. K.; Lindenberg, T. Ia.; Kostetskaia, T. V.; Shmel'kova, V. I.; Bershtein, L. M.; Smida, Iu. *Vopr Onkol* 25(2): 42-44; 1979.

To evaluate the effects of various hormones on oncornavirus replication, chick embryo cells [group-specific (gs) antigen-negative] growing in monolayer were inoculated with Rous sarcoma virus (RSV) and 30 min later, exposed to medi-

um containing estradiol (1 $\mu\text{g/ml}$), testosterone (5 $\mu\text{g/ml}$), hydrocortisone acetate (10 or 40 $\mu\text{g/ml}$), thyroxine (3 $\mu\text{g/ml}$), or insulin (2 $\mu\text{g/ml}$). The presence of Gs antigen in the fibroblast cultures was assessed by complement fixation. Twelve chick embryo cell cultures were tested. Gs antigen was present in 3/12 cultures exposed to testosterone, 2/12 cultures exposed to estradiol, and in 1/12 cultures exposed to thyroxine. Inoculation of chickens with culture medium collected during the first 5 days of incubation with hormones did not result in tumor formation. (4 refs)

- 79-2136 **Monomer and Multimer Covalently Closed Circular Forms of Rous Sarcoma Virus DNA.** (Eng) Goubin, G. (Dept. Cellular Biology, Inst. Cancerology and Immunogenetics, Villejuif, France); Hill, M. *J Virol* 29(2): 799-804; 1979.

Monolayer cultures of chicken embryo fibroblasts were infected with the Schmidt-Ruppin strain of Rous sarcoma virus (RSV), subgroup D, or its temperature-defective derivative (*tsSR-D*), and the purified form I RSV DNA isolated 30 hr after infection was analyzed by neutral sucrose gradient sedimentation. The covalently closed circular molecules of viral DNA synthesized in the virus-infected cells were composed mainly of monomers sedimenting at 22S-27S. These monomers were detected by annealing with ^3H -labeled complementary DNA or by transfection assays. However, 11% of the infectious circles sedimented faster than the monomers. There was a peak at 32S that may correspond to dimer molecules. Traces of infectivity (about 3%) found between 32S and 65S suggest the presence of higher oligomers. In alkaline sucrose gradients, covalently closed monomers were found at 64S-71S. Transfection assays showed that the monomers were infectious, although alkali treatment reduced their infectivity to less than one-tenth of that found at neutral pH. Perhaps for this reason, no infectious dimers or higher oligomers were observed. Upon resedimentation, the 95S dimers could be separated from the monomers and detected by hybridization. (27 refs)

- 79-2137 **In Vitro, the Major Ribosome Binding Site on Rous Sarcoma Virus RNA Does Not Contain the Nucleotide Sequence Coding for the N-Terminal Amino Acids of the gag Gene Product.** (Eng) Darlix, J. L. (Departement de Biologie Moléculaire, Université de Genève, CH-1211 Geneva 4, Switzerland); Spahr, P. F.; Bromley, P. A.; Jatton, J. C. *J Virol* 29(2): 597-611; 1979.

Ribosome binding experiments with Rous sarcoma virus (RSV) RNA were performed with the use of a nuclease-treated reticulocyte lysate in order to determine directly whether the in vitro translation of the first gene (*gag*) is initiated within the same hundred nucleotides that are first reverse-transcribed in vitro. In addition, the length and the nucleotide sequence of the RSV RNA ribosome binding site were deter-

mined. Ribosomes from the reticulocyte lysate bound strongly and mainly to a region located in the 5' end of the RSV RNA molecule, between residues 9 and 53. This binding involved the participation of initiator transfer RNA and was sensitive to inhibitors of protein synthesis such as 7-methyl-guanosine monophosphate and aurintricarboxylic acid. The nucleotide sequence of this ribosome binding site contained a GUG codon centered at position 26 that was not in phase with any termination codon within the 5'-end nucleotide sequence of the RNA analyzed (101 residues). However, the predicted N-terminal amino acid sequence starting from this GUG codon (or even from any AUG or GUG codon in the 5' end of the RNA) did not coincide with that of the in vitro-synthesized product of the 5'-end proximal *gag* gene. Nevertheless, inhibition of ribosome binding to this site was accompanied by an inhibition of the in vitro translation of the *gag* gene. (36 refs)

- 79-2138 **Antigenic Determinants Specific to the Envelope Glycoprotein of Exogenous Avian Tumor Viruses.** (Eng) Marini, S. C. (Wistar Inst. Anatomy and Biology, Philadelphia, PA, 19104); Friis, R. R.; Halpern, M. S. *J Virol* 29(2): 805-807; 1979.

The immunogenicity of the envelope glycoprotein (VGP) of exogenous avian sarcoma virus (ASV) was assessed in 15B x 7₂ chickens positive (V+) for subgroup E endogenous Rous-associated virus (RAV-0). At 4 wk posthatch, several days after the collection of preinfection sera, eight of the V+ chickens were infected with the Prague strain of Rous sarcoma virus, subgroup A, and seven were infected with B₁₇ virus, subgroup C. Seven chickens were left uninfected. Serum samples were obtained 2 wk after infection and at 2-wk intervals thereafter. Antibody reactivity in the various sera to determinants of VGP was measured by indirect immunoprecipitation. As measured with viral test antigens of subgroups A, B, C, and D, increased levels of radioactivity, compared with preinfection levels, were detected in immune precipitates prepared with postinfection sera of infected V+ chickens. In tests of these sera against subgroup E VGP, a markedly reduced or negligible increase in precipitable radioactivity was detected relative to the increase measured with exogenous VGP. Little or no increase in precipitable radioactivity was measured with sera of uninfected V+ chickens. In virus neutralization assays, the sera of uninfected V+ chickens did not neutralize viruses of subgroups A-E. Postinfection sera of infected V+ chickens did not neutralize subgroup E virus and only neutralized exogenous virus of the same subgroup as that of the infecting virus. The immunoprecipitation and neutralization assays show that antibody in the sera of infected V+ chickens recognizes nonneutralizing determinants that, at least collectively, are present on the VGP of several, if not all, exogenous viruses. The absence of these determinants from the VGP of RAV-0 serves to distinguish them from group-specific determinants. These determinants, therefore, fall into a classification category in which cross-reactivity on non-group-specific determinants spans two or more subgroups. (9 refs)

79-2139 Nature of Rous Sarcoma Virus-specific RNA in Transformed and Revertant Field Vole Cells. (Eng) Krzyzek, R. A. (Dept. Microbiology, Univ. Minnesota Medical Sch., Minneapolis, MN, 55455); Lau, A. F.; Faras, A. J. *J Virol* 29(2): 507-516; 1979.

To determine the size classes of virus-specific RNA present in Rous sarcoma virus-transformed and revertant field vole cells, cytoplasmic and polyribosomal RNA's from these cells were fractionated by rate-zonal sedimentation and hybridized with a ³H-labeled complementary DNA viral probe. In contrast to Rous sarcoma virus-infected permissive avian cells, only two of three discrete species of virus-specific RNA were detected in the cytoplasm of these vole cells. They included genome-length 35S RNA and a 21S RNA. Viral 28S RNA, routinely detected in the cytoplasm of productively infected avian cells, could not be found. In addition, a low-mol-wt viral RNA sedimenting at < 16S was detected in both infected avian and vole cells. Because of its heterogeneity, this latter species is most likely generated from the intracellular degradation of the larger viral RNA's. The viral 35S and 21S RNA's were found to be associated with the total polyribosomes from these vole cells. Studies were also performed to determine the distribution of total viral genomic and sarcoma-specific RNA sequences among the size classes of fractionated total polyribosomes. In both transformed and revertant vole cells, most of the cytoplasmic viral RNA sequences were also associated with all size classes of the total polyribosomes, and the two cell types distributed similarly. Sarcoma-specific sequences were present on both the 35S and 21S RNA species. These data suggest that the expression of the viral transforming gene in revertant field vole cells may be controlled at some stage subsequent to translation of the viral RNA. (32 refs)

79-2140 Phenotypes of Rous Sarcoma Virus-transformed Fibroblasts: An Argument for a Multifunctional Src Gene Product. (Eng) Friis, R. R. (Justus-Liebig-Universität, Institut für Virologie, Frankfurter Strasse 107, D-6300 Giessen, W. Germany); Schwarz, R. T.; Schmidt, M. F. *Med Microbiol Immunol (Berl)* 164(1/3): 155-165; 1977.

Speculations concerning the nature and function of the *src* gene product of Rous sarcoma virus are made on the basis of studies of the phenotypes of transformed cells. It is believed that the phenotypic differences reproducibly observed in cell cultures infected with different transformation-defective mutants must be derived from mutations in the *src* gene and consequent changes in its function. These functional changes may be quantitative or qualitative. There is an analogy between *src* and *pol*, the genetic unit coding for reverse transcriptase. Of all mutants in RNA tumor virus replication or transformation, the majority have been transformation defective; thus, they are presumably defective in *src*. Of the remainder, 90% have been defective in *Pol*. Multifunctional proteins may respond at higher probability to each mutation because

a high precision of protein conformation is required, although this hypothesis has not been proved. Changes in the function of the *src* gene product may be qualitative rather than quantitative, as some mutants grow logarithmically at 42 C without exhibiting a transformation-specific increase in hexose transport. In the presence of tunicamycin, the same mutants show increased hexose transport when shifted to the permissive temperature (35 C). Since this compound affects glycosylation, the *src* gene product must be independent of this reaction. (21 refs)

79-2141 Neural Crest Cells: Temperature-dependent Transformation by Rous Sarcoma Virus. (Eng) Greenberg, J. H. (Lab. Developmental Biology and Anomalies, Natl. Inst. Dental Res., NIH, Bethesda, MD, 20014); Bader, J. P. *Cell Differ* 8(1): 19-27; 1979.

The effects of infecting cultured neural crest cells from chick embryos with a mutant (RSV-BH-Ta) of the Bryan high-titer strain of Rous sarcoma virus (RSV) before or after their morphological differentiation into pigmented cells were studied. Uninfected cells proliferated slowly. Infection with the mutant before differentiation (culture day 2) at either the permissive (37 C) or the nonpermissive temperature (41 C) dramatically stimulated cell proliferation, although at 41 C growth appeared to stop after several weeks. At the permissive temperature, the neural crest cells acquired extensive vacuoles and were greatly enlarged in comparison with uninfected cells or infected cells grown at 41 C. These characteristics are similar to those of fibroblasts (FB) transformed with RSV-BH-Ta at 37 C. At the nonpermissive temperature, infected cells were not vacuolated and differed slightly in appearance from that of uninfected cells. However, even at confluency they did not show the characteristic morphology of untransformed FB or RSV-BH-Ta-infected FB at 41 C. Infection at either temperature prevented the neural crest cells from differentiating morphologically into pigmented cells or into any other derivatives previously observed in culture. Infection of the cells after they had differentiated into pigment cells induced rapid cell proliferation at both temperatures. In addition, these cells lost their pigment granules and, after 1-2 wk, were morphologically indistinguishable from those infected before they had differentiated. The results of infection of neural crest cells with a virus that induces a temperature-dependent transformation demonstrate that even at the nonpermissive temperature, the virus has an effect on cell growth and morphology and it may be actively involved in regulating the state of differentiation of certain types of cells. (20 refs)

79-2142 In Vitro and In Vivo Properties of Neoplastic LEW/CUB Cells. (Eng) Vesely, P. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, Prague, Czechoslovakia); Kren, V.; Wyke, J.; Jirasek, A.; Elleder, M.; Bannikov, G. *Folia Biol (Praha)* 24(6): 392-394; 1978.

LEW/CUB rat cells transformed by the avian sarcoma viruses (ASV), SR-RSV-D, B77, and LA334 (a temperature-sensitive mutant of B77) were studied with respect to malignancy in vivo and behavior in vitro. Mixed embryo fibroblasts (F cells), male embryo liver cells (L cells), male embryo kidney cells (K cells) and their two clones (A, G cells) were transformed and the following characteristics established: pattern of virus rescue, efficiency of plating on a solid substratum and in soft agar, tumorigenicity in syngeneic rats, population doubling time, and behavior in vitro. Almost all the transformed clones yielded pleiomorphic sarcomas when injected sc (10^6 cells) into adult syngeneic LEW/CUB rats. The tumorigenic cells generally manifested the transformed morphotype and anchorage independence, with the exception of F cells infected with B77 or SR-RSV-D, kidney cells infected with B77 and A cells infected with LA334. These cells did not grow in soft agar. With one exception (G cells infected with B77) all the virogenic cells were tumorigenic. All the tumors appearing after injection of LEW/CUB cells transformed by ASV in vitro were noninvasive, which correlated with their behavior in vitro. (3 refs)

- 79-2143 New Endogenous RNA Tumor Viruses.** (Eng) Chen, Y. C. (Dept. Biological Sciences and Genetics Center, North Texas State Univ., Denton, TX, 76203). *Tex J Science* 30(5, Suppl): 3-12; 1978.

New endogenous RNA tumor viruses obtained from cells of members of the avian family, Phasianidae, were studied. Helper activity for the defective Bryan high-titer strain of Rous sarcoma virus (RSV) was found in normal embryo fibroblast cultures of Ghighi, Green, Silver, Mongolian, and Swinhoe pheasants, Chinese quail, and Chukar (Stone partridge). All but one of the new pseudotypes failed to produce foci in mammalian cell cultures; Chinese quail virus induced foci on European field vole and mouse cells with high efficiency. The polycation, Polybrene, enhanced foci formation on chicken cells infected with the new RSV pseudotypes. The viruses from Mongolian and Swinhoe pheasant, Chinese quail, and Chukar cells specified unique envelope determinants, and a leukosis helper virus, capable of inducing specific homologous pseudotype interference, was recovered from the Swinhoe pheasant and Chinese quail viruses. The Mongolian pheasant and Chukar viruses did not yield isolatable leukosis helper virus. Helper activity and spontaneously released endogenous virus were isolated from Chinese quail, Golden pheasants, and Ghighi pheasants, but not from the other species. Spontaneously released Chinese quail virus and the new RSV pseudotype from Chinese quail showed the same interference pattern. Plaques were produced by the pseudotypes from Chinese quail and Swinhoe pheasant cells, but not by any of the spontaneously produced viruses. Thus, the spontaneous viruses and their RSV pseudotypes are not genetically identical. (17 refs)

- 79-2144 Immunological Characterization of the RNA-dependent DNA Polymerase from Reticuloendothelial Virus.** (Eng) Moelling, K. (Max-Planck-Institut für Molekulare Genetik, D-1000 Berlin-Dahlem, W. Germany). *Med Microbiol Immunol (Berl)* 164(1/3): 115-118; 1977.

Immunological characterization of the RNA-dependent DNA polymerase (RDDP) from avian reticuloendotheliosis virus (REV) demonstrated that it was not related to the RDDP's from other known avian RNA tumor viruses. The structure, optimum ion requirements, and serology of the REV polymerase resembled those of the RDDP's from murine tumor viruses. However, much larger amounts of antiserum were required to inhibit the REV polymerase. Apparently, REV is not a genuine murine virus growing in avian cells; rather it seems to have undergone some process of adaptation to the new host. (6 refs)

- 79-2145 No Homology Detectable Between Marek's Disease Virus (MDV) DNA and Herpesvirus of the Turkey (HVT) DNA.** (Eng) Kaschka-Dierich, C. (Institut für klinische Virologie der Universität, Loschgestrasse 7, D-852 Erlangen, W. Germany); Bornkamm, G. W.; Thomssen, R. *Med Microbiol Immunol (Berl)* 165(4): 223-239; 1979.

The relatedness of four strains of Marek's disease virus (MDV) and two strains of herpesvirus of turkey (HVT) was analyzed by gel electrophoresis of viral DNA digested by site-specific endonucleases and by filter hybridization of viral DNA with complementary RNA (cRNA). The four MDV strains (1 pathogenic, 1 attenuated, and 1 apathogenic) showed fragment patterns completely different from those of the two HVT strains upon digestion of the viral DNA with *Bam*HI, *Eco*RI, *Hind*III, *Hpa*I, and *Xho* and separation of the fragments on agarose gels. Among the four MDV strains, the cleavage patterns showed great similarities as well as some slight differences. This was also true for the HVT strains. Filter hybridization of viral DNA with labeled cRNA prepared from MDV (strain GA) DNA or from HVT (strain PH-THV1) DNA HVT revealed no cross-hybridization between the MDV and HVT strains. It is estimated that the amount of homologous sequences in the MDV and HVT strains must be <3%-5% of the whole genome. This result was not expected, since both types of viruses are known to be antigenically related. (29 refs)

- 79-2146 Detection of Lucke Herpes Virus Antigens in Infected Frog Pronephric Cells.** (Eng) Tweedell, K. S. (Dept. Biology, Univ. Notre Dame, Notre Dame, IN, 46556); Mizell, M. *Arch Virol* 59(3): 239-249; 1979.

Antiserum to purified Lucke tumor herpes virus (LTHV) was used to detect Lucke herpes virus antigens in frog pronephric

(WMPA) cells infected with herpes virus derived from Lucke renal carcinomas of *Rana pipiens*. After application of LTHV antiserum, specific indirect immunofluorescence appeared in the cytoplasm, but not the nuclei, of virus-infected cells cultivated at 25 or 9 C; the former temperature was optimum for cell cultivation, whereas the latter was in the permissive range for virus induction. Normal WMPA cells treated with LTHV antiserum demonstrated neither cytoplasmic nor nuclear fluorescence at 25 or 9 C. Newly infected cells, in addition to showing cytopathic effects in tissue culture, produced either nuclear or cytoplasmic fluorescence, and virus activity was corroborated by electron microscopy (EM). Later cell passages produced only cytoplasmic fluorescence. In one infection, distinct and singular cytoplasmic fluorescence was correlated with scattered cytoplasmic herpes viruses and with groups of dense granular aggregates in the nuclei, as demonstrated by EM. The data suggest that after the initial isolations and early viral passages of LTHV in the pronephric cells, virus replication was either essentially arrested in most cells or it continued at a level insufficient to cause general cell lysis. (14 refs)

- 79-2147 Virus Precursor Shedding from Mammary Tumor Cells.** (Eng) McClelland, A. J. (Lab. Veterinary Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY). *Nature* 277(5691): 13; 1979.

The precursor molecule (pre-gp 70) of murine mammary tumor virus (MuMTV) glycoproteins is shed uncleaved from the surface membrane of tumor cells in which it is synthesized. However, labeling studies have shown that pre-gp70 is not present on the surface of MuMTV-producing cells. This indicates that two populations of pre-gp70 may exist: one destined to be cleaved and inserted into the membrane for virus assembly, and one that is shed without cleavage. This shedding may help MuMTV-producing cells escape host immune defenses. (no refs)

- 79-2148 Integration and Transcription of Mouse Mammary Tumor Virus DNA in Rat Hepatoma Cells.** (Eng) Ringold, G. M. (Dept. Pharmacology, Stanford Univ. Medical Sch., Stanford, CA, 94305); Shank, P. R.; Varmus, M. E.; Ring, J.; Yamamoto, K. R. *Proc Natl Acad Sci USA* 76(2): 665-669; 1979.

The observation that mouse mammary tumor virus (MMTV) gene expression is not simply a function of the dosage of viral DNA sequences in infected rat hepatoma cells (HTC) prompted an investigation of the structure and organization of the viral sequences that are integrated into the host genome. HTC 4.1 cells were infected with MMTV at multiplicities of infection ranging from approx 10^1 to 10^5 particles/cell. It is known that HTC cells infected with MMTV acquire viral DNA that becomes covalently linked to the cell DNA. Infected cell DNA's were cleaved with restriction en-

donucleases, the DNA fragments were separated electrophoretically, and fragments containing viral sequences were identified by molecular hybridization. The data presented demonstrate that there are many sites in cell DNA into which MMTV DNA integrates, that the junctions between viral and cellular DNA occur within a limited portion of the viral genome, that clones that contain MMTV DNA do not necessarily produce viral RNA, and that the extent of transcription and glucocorticoid responsiveness of MMTV proviruses may be dependent on the site(s) in cell DNA in which the viral DNA resides. Although there are many integration sites for MMTV DNA in HTC cell DNA, there appears to be a unique site on the viral genome that becomes linked to cellular DNA. (33 refs)

- 79-2149 Integration of the DNA of Mouse Mammary Tumor Virus in Virus-infected Normal and Neoplastic Tissue of the Mouse.** (Eng) Cohen, J. C. (Dept. Microbiology and Immunology, Tulane Univ., New Orleans, LA, 70112); Shank, P. R.; Morris, V. L.; Cardiff, R.; Varmus, H. E. *Cell* 16(2): 333-345; 1979.

Restriction endonucleases that cleave the DNA of mouse mammary tumor virus (MMTV) at one site (Eco RI) and at several sites (Pst I, Sac I, and Bam HI) were used to study infection and mammary tumorigenesis in mice. Proviruses (PV's) acquired during infection of BALB/c mice foster-nursed by virus-producing C3H females could be distinguished from the MMTV PV's endogenous to uninfected BALB/c mice by the fragments generated with Pst I and Bam HI. It was found that lactating mammary glands as well as mammary tumors from BALB/cfC3H mice acquired MMTV DNA and that a minimum of approx 10% of normal glandular cells were infected. The new PV's appeared to be linked to cellular DNA of mammary tumors and infected lactating mammary glands within a limited region (0.2×10^6 daltons) of the viral DNA. The location of this region, based upon mapping studies with unintegrated MMTV DNA, suggests that the orientation of these PV's is colinear with linear DNA synthesized in infected cells and thus approx colinear with viral RNA. A large number of sites in the cellular genome can accommodate a new PV; the acquired PV's are rarely, if ever, found in tandem with each other or with endogenous PV's. However, random integration and integration into a large number of preferred sites in the host genome cannot be distinguished. Since Eco RI and Bam HI cleavage of DNA from each mammary tumor generates a unique set of viral-specific fragments, it is proposed that the tumors are composed principally of cells derived from a subset of the many infected cells in a mammary gland. This proposal is supported by the finding that Eco RI digestion of DNA from several transplants of a primary tumor yields a pattern characteristic of the primary tumor. (26 refs)

- 79-2150 Murine Mammary Tumor Virus Expression During Mammary Tumorigenesis in BALB/c Mice.** (Eng) Pauley, R. J. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX, 77030); Medina, D.; Socher, S. H. *J Virol* 29(2): 483-493; 1979.

Hormone-induced BALB/c hyperplastic alveolar nodule (HAN) lines, which were established from primary HAN induced in BALB/c mice by hormonal stimulation alone or in combination with 7,12-dimethylbenz(a)anthracene (DMBA), and mammary tumors that arose in the HAN lines were examined for murine mammary tumor virus (MuMTV) expression. MuMTV expression was quantitated by molecular hybridization with a complementary DNA (cDNA) probe representative of the MuMTV genome. The D1 and D2 HAN lines, which originated in mice that had pituitary isografts alone (D2) or in combination with estradiol-17 β (D1), contained detectable amounts of hybridizable MuMTV sequences. MuMTV RNA sequences were also observed in 5/6 transplanted BALB/c mammary tumors examined. The D1 HAN line and the mammary tumors that arose from it contained approx 0.01% MuMTV-specific RNA sequences. The D2 HAN line and its mammary tumors contained appreciable amounts of MuMTV RNA, approx 0.13% of the total cellular RNA, a level that was similar to that in spontaneous mammary tumors from BALB/cfC3H mice. The D2 HAN line as well as the D2, C4 (hormone- + DMBA-induced), and CD8 (DMBA-induced) mammary tumors accumulated RNA that was apparently homologous to most of the MuMTV genome. Thermal denaturation of hybrids indicated extensive sequence homology between the MuMTV cDNA and hybridizable RNA in the BALB/c HAN lines and mammary tumors. A low level of C-Type viral RNA was observed in the BALB/c HAN lines and most mammary tumors by molecular hybridization with a cDNA to Moloney murine leukemia virus. These data demonstrate that MuMTV sequences are frequently expressed in hormone-induced BALB/c HAN lines and the mammary tumors derived from them and in the ductal hyperplasias induced in BALB/c mice by hormones and/or a chemical carcinogen. The transition from the preneoplastic to the neoplastic state in BALB/c mice does not appear to be due to a change in the steady-state levels of MuMTV RNA, since the hormone-induced HAN lines and mammary tumors had similar levels of hybridizable MuMTV RNA. - 79-2151 Immunological Cross Reaction Between Sera from Patients with Breast Cancer and Mouse Mammary Tumor Virus.** (Eng) Imai, M. (Lab. Ultrastructure Res., Aichi Cancer Center Res. Inst., Kanokoden, Tashiro-cho, Nagoya 464, Japan); Yamada, C.; Saga, S.; Nagayoshi, S.; Hoshino, M. *Gann* 70(1): 63-74; 1979.

Sera from 89 Japanese breast cancer (BC) patients, 5 patients with benign mammary hyperplasia (BMH), 40 patients with neoplastic diseases other than breast cancer (NBC), and 68 healthy women (controls) were examined by immunofluores-

cence (IF) tests using cultured mouse mammary tumor tissue (MMT) producing mouse mammary tumor virus (MMTV). A positive reaction with MMT cells was obtained with 55.1% of the BC sera, 60% of the BMH sera, 30% of the NBC sera, and 26.5% of the control sera. Only the BC sera gave a significantly higher frequency of positive reactions than the control sera. Sera that were positive in the IF test with MMT cells did not react with MMTV-negative mouse cell lines. The distribution pattern of the specific fluorescence obtained with the positive sera was similar to that obtained with rabbit antiserum to A-type particles. The results of absorption studies and blocking tests also suggested that the reaction was due to antigenic components common to A- and B-type particles. The results of membrane IF tests suggested that some human sera also reacted with envelope antigen(s) of B particles. Antinuclear antibodies were found in 15.7% of the BC sera by IF; most of these sera did not contain antibodies that cross-reacted with MMTV. It is not known what role the antibodies to MMTV detected in human sera have in the development of BC. (31 refs)

- 79-2152 Structural Proteins of C-Type RNA Leukemia Viruses and Autoimmune Diseases of New Zealand Mice--Biochemical Analysis of MuLV Structural Proteins in the Serum and MuLV Cell-Surface Antigens Detectable by Endogenous Antibody.** (Jpn) Yoshiki, T. (Dept. Pathology, Sapporo City General Hosp., Sapporo, Japan); Hayasaki, T.; Itoh, T.; Shirai, T.; Ikeda, H.; Katagiri, M. *Virus* 28(2): 103-111; 1978.

The murine leukemia virus (MuLV) structural proteins in mouse serum were analyzed by affinity chromatography and sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), and MuLV cell-surface antigens were characterized immunologically. Glycoprotein 70 (gp70)-related molecules in the serum of New Zealand mice occurred as an immune complex and consisted of three gp fragments with an approx mol wt of 53,000 (53K), 45K, and 32K, respectively. In contrast, gp70 isolated from the surface of infected cells was a single gp molecule with a wt of approx 70K. The mol wt of the major gp70 activity in serum fractionated by Sephadex gel filtration ranged from 120K to 140K. The minor gp70 activity was the same size as serum albumin. The results suggest that the three gp fragments of serum gp70 might have resulted from a specific transcriptional, translational, or post-translational process or from nonspecific proteolysis at susceptible sites. It is possible that a gp70-related molecule in the serum is a specific envelope-related gp that consists of three gp fragments with a mol wt 53K, 45K, and 32K, respectively, that serum gp70 is associated with host cellular components, or that it is present as a dimer. Pooled sera from 2- and 9-mo-old B/WF₁ mice were fractionated by Sephadex gel filtration. The major gp70 activity of 2-mo-old serum was found in fractions with a mol wt of 120-140K; that of 9-mo-old serum eluted mainly at the void volume. Most of the gp70-related molecules in the serum of the aged mice were probably present as immune complexes. In attempts to identi-

fy the molecule(s) bearing the antigenic determinants for endogenous antibody to MuLV or Gross-MuLV natural antibody (GNA), ¹²⁵I-labeled MuLV proteins were subjected to immunoprecipitation with GNA-positive mouse sera. SDS-PAGE of the resulting precipitates revealed that the major molecule bearing antigenic determinants for GNA was p(85), the precursor polypeptide of the MuLV core structural proteins p30, p15, and p10. (19 refs)

- 79-2153 Search for Type C Virus-Like Information in Normal, Benign and Malignant Human Prostatic Tissues.** (Eng) Kouttab, N. M. (Dept. Molecular Carcinogenesis and Virology, The Univ. Texas System Cancer Center, M.D. Anderson Hosp. Tumor Inst., Houston, TX, 77030); Bowen, J. M.; Dmochowski, L.; vonEschenbach, A.; Bracken, R. B.; Johnson, D. *Tex J Science* 30(5, Suppl): 139-148; 1978.

A competition radioimmunoassay (RIA) for C-type virus interspecies p30 antigen was used to determine whether murine leukemia virus (MuLV) p30-like antigens were present in normal, benign hyperplastic (BHP), or malignant (PCa) human prostate. Five of 17 BHP and 4/22 PCa tissue extracts were positive for the interspecies p30 antigen, but not for intraspecies p30 antigen. None of 10 normal tissue extracts was positive for either antigen. The positive results obtained with the BHP and PCa tissues were specific and apparently not due to enzymes such as proteases. Thus, it may be possible to separate RIA reactions that are specific for p30 interspecies antigen from reactions that may be due to protease activity. The data suggest that C type-like viral information may be present in human BHP and PCa tissues. (19 refs)

- 79-2154 Analysis of the Genomes of Leukemia Viruses of the AKR Mouse.** (Eng) Rommelaere, J. (Dept. Biology, Center Cancer Res., Massachusetts Inst. Technology, Cambridge, MA, 02139); Faller, D. V.; Hopkins, N. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 561-575; 1978.

The RNA genomes of the AKR mouse ecotropic N-tropic viruses Akv-1 and Akv-2, and four recombinant mink cell-focusing (MCF) viruses were studied by T1 RNA fingerprinting and oligonucleotide mapping. The MCF viruses were shown to share 75% of their large T1-resistant oligonucleotides with Akv-1 and -2 and to possess some large oligonucleotides not found in Akv viruses. Each MCF isolate differed in the number of large T1 oligonucleotides shared with Akv and in the number of MCF-specific oligonucleotides that it possessed. The Akv oligonucleotides missing in MCF fingerprints and MCF-specific oligonucleotides not found in Akv T1 fingerprints were clustered at corresponding regions of the Akv and MCF genomes in pooled data maps, as would be expected if MCF viruses arise by recombination involving an Akv virus. The biological properties of MCF

viruses indicated that they possess altered glycoprotein 70 (gp70) proteins relative to the Akv viruses. At least three, and possibly four, of the MCF isolates are missing Akv oligonucleotides starting at oligonucleotide map position 21. These observations suggest that the portions of the Akv and MCF genomes corresponding to map positions 21-27 contain sequences that code for gp70 and that are involved in determining the host range of the virus. It has been suggested that MCF's, rather than the ecotropic viruses, are the 'real' leukemogens in leukemia-susceptible mice and that the presence of a recombinant gp70 protein on the surface of lymphocytes may be the cause of their alteration to a transformed phenotype. (22 refs)

- 79-2155 AKR-MuLV-associated Cell Surface Antigens.** (Eng) Ihle, J. N. (Basic Res. Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Longstreth, J. D.; Pazmino, N. H.; McLellan, W. L.; Hanna, M. G. *Med Microbiol Immunol (Berl)* 164(1/3): 179-195; 1977.

The expression of AKR murine leukemia virus (MuLV)-associated cell-surface antigens was studied using antisera produced by immunization with either intact virus or virus-replicating cells. The type specificity of rabbit antisera to the purified viral antigens of AKR virus was indicated by reaction of each antiserum with its homologous protein and not with other virion components, by the inability of the antisera to neutralize Rauscher leukemia virus (RLV), and by the inability of the antisera to react significantly with the purified, iodinated RLV glycoprotein gp71. Titration data using purified AKR proteins indicated that they are excellent reagents for analyzing antigens recognizable by autogenous immune or monospecific hyperimmune sera. The specificity of the reactivities of the monospecific antisera to the individual AKR proteins was established by radioimmunoassay, and thus the distinctive reactivities could be used to characterize the expression of virus-associated antigens on the surface of virus-infected cells. The results using these specific reagents demonstrated that of the virion components examined, only gp71 and p12 were consistently expressed on the cell surface. The anti-AKR gp71 also labeled the virion sites on Gross leukemia virus-positive (G+) cells; the anti-AKR p12 labeled only the cell-surface sites of G+ cells. There are no data to explain why antibody to p12 recognizes the cell surface but not the virion. The results indicate that the expression of viral proteins gp71 and p12 on tumor cell surfaces may be a widespread phenomenon. (29 refs)

- 79-2156 Transfection by Exogenous and Endogenous Murine Retrovirus DNAs.** (Eng) Copeland, N. G. (Sidney Farber Cancer Inst., Boston, MA, 02115); Cooper, G. M. *Cell* 16(2): 347-356; 1979.

DNA transfection was used to study the endogenous re-

trovirus genomes inherited by uninfected mouse cells. Quantitative assays for infectious DNA's of ecotropic (ET) and xenotropic (XT) murine leukemia viruses (MuLV's) were developed using donor DNA's of cells that were exogenously infected with ET Moloney, AKR, or BALB MuLV's or with XT AKR, BALB, or NZB MuLV's. The DNA's of cells exogenously infected with ET MuLV's had specific infectivities of approx 0.5 infectious unit (IU)/ μ g DNA in transfection assays on NIH/3T3 cells. The DNA's of cells exogenously infected with XT MuLV's had specific infectivities of approx 0.2 IU/ μ g DNA in transfection assays on mink CCL64 cells. In contrast, the DNA's of uninfected NIH/3T3, BALB/3T3, and AKR-2B mouse cells were noninfectious when assayed for infectious endogenous ET MuLV DNA's (< 0.001 IU/ μ g DNA). Similarly, the infectivities of XT MuLV DNA's of uninfected NIH/3T3, BALB/3T3, AKR-2B, and NZB-Q mouse cells were > 100 -fold lower than the infectivities of DNA's of XT MuLV-infected cells. Furthermore, the DNA's of BALB/3T3 cells transformed by Kirsten murine sarcoma virus (MSV) or by simian virus 40 (SV40) were noninfectious for ET or XT MuLV, although these cells contained infectious transforming DNA's of MSV or SV40. The endogenous MuLV genomes of uninfected mouse cells thus appeared to differ from the MuLV proviruses of MuLV-infected cells. These results are consistent with the hypothesis that endogenous MuLV genomes are linked to cellular DNA sequences that result in both inefficient transcription of endogenous MuLV genomes and the reduced infectivity of endogenous MuLV DNA's in transfection assays. (56 refs)

- 79-2157 Quantitative Measurement of Intracellular RNA Genomes of Rauscher Murine Leukemia Virus by Competition Hybridization in DNA Excess.** (Eng) East, J. L. (Dept. Molecular Carcinogenesis, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Chan, J. C.; Bartlett, R. J.; Knesek, J. E. *J Virol* 29(2): 818-824; 1979.

The technique of competition hybridization in DNA excess was used to determine the intracellular distribution of RNA genomes of Rauscher murine leukemia virus and to determine the proportion of polyadenylated (poly A+) and non-polyadenylated (poly A-) viral RNA genomes that exist in total cellular RNA. The retrovirus-producing JLS/V5 cell line derived from BALB/c mouse spleen-thymus cells was used as the source for viral and intracellular RNA. An examination of subcellular RNA fractions revealed that 59% of intracellular viral RNA genomes were associated with the nuclear-enriched fraction, 41% with the cytoplasmic fraction, and 18% with the polysomal-enriched fraction. Also, an analysis of total cellular RNA disclosed that 20% of intracellular viral RNA genomes were poly A+ and 80% were poly A-. (29 refs)

- 79-2158 Regulation of Erythroid Differentiation: Characterization of Rauscher and Friend Virus-transformed Proerythroid Cells.** (Eng) Miao, R. M. (Life Sciences Div., SRI International, Menlo Park, CA, 94025); Fieldsteel, A. H. *Proc Soc Exp Biol Med* 160(1): 24-27; 1979.

The regulation of erythroid differentiation in proerythroid cell lines transformed by Friend virus (FV-BALB and FV-BDF₁) and Rauscher virus (RV-187 and RV-133) was studied. The benzidine assay for Hb was used to determine differentiation. RV-133 and RV-187 were induced to differentiate in the presence of eight known inducers: dimethyl sulfoxide, dimethylformamide, N-methylformamide, pyridine-N-oxide, butyric acid, hypoxanthine, acetamide, and N-methylpyrrolidone (NMP). The level of differentiation and the dose responses were different for the two cell lines and the various inducers. The FV-BALB line responded to only one of these inducers, NMP, even when the other inducers were added in cytotoxic concentrations. The second FV-transformed cell line, FV-BDF₁, did not respond to any of the inducers, even in cytotoxic concentrations. (27 refs)

- 79-2159 The Resistance of G Mouse Fibroblasts to Murine Leukemia Virus Infection.** (Eng) Kai, K. (Dept. Genetics, Inst. Medical Science, Univ. Tokyo, Shirokanedai, Minato-ku, Tokyo 108, Japan). *Jpn J Exp Med* 48(5): 459-462; 1978.

Mouse strain G cells, which are resistant to N- and NB-tropic Friend leukemic viruses (FLV's), FLV-susceptible DDD mouse cells, Fv-1 restricted BALB/c mouse cells, and non-permissive chick C/BE cells were examined for adsorption and penetration of ³²P-labeled N-tropic FLV. G mouse cells permitted viral adsorption and penetration as efficiently as the other mouse cells. The nonpermissive chick cells permitted adsorption as efficiently as mouse cells early after infection, but later the adsorption rate became slower. The chick cells also permitted penetration at a slower rate than mouse cells. Thus, the resistance of G mouse cells is not expressed in the adsorption or penetration steps. In the XC plaque assay, plaques in the G mouse fibroblasts were markedly smaller than those in other mouse fibroblasts, suggesting that there may be an inefficient propagation of the virus to surrounding cells. G, DDD, and BALB/c mouse embryo cells were infected with N-tropic FLV at a multiplicity of infection of 0.003, and the virus-producing cell population was estimated at intervals after infection. In G mouse cells, the increase in the virus-producing cells 6 days after infection was < 3 -fold, but in the DDD and BALB/c mouse cells the increase was 70-fold. These results suggest that the restriction of G mouse fibroblasts to MuLV is not in the first cycle of infection but in the propagation of the virus to the surrounding cells. (14 refs)

79-2160 Transformation of DBA/2 Mouse Fetal Liver Cells Infected In Vitro by the Anemic Strain of Friend Leukemia Virus. (Eng) Golde, D. W. (Div. Hematology and Oncology, Univ. California Sch. Medicine, Los Angeles, CA, 90024); Bersch, N.; Friend, C.; Tsuei, D.; Marovitz, W. *Proc Natl Acad Sci USA* 76(2): 962-966; 1979.

This study was designed to determine whether Friend leukemia virus (FLV) can transform hematopoietic cells in vitro and whether spleen focus-forming virus (SFFV) is essential for that event to occur. Fetal liver cells of DBA/2 mice were infected with the anemic strain of FLV (FLV-A), which has no SFFV activity. The infected cells were grown in medium with or without erythropoietin. Transformed lines were isolated only from the infected cultures that had been treated with erythropoietin at the time of their initiation. The properties of three permanent cell lines in serial passage for > 2 yr are described. Each has an aneuploid karyotype. Only the immature hematopoietic cells of the first line have metacentric chromosomes. They grow in suspension, as do the erythroleukemic lines derived from leukemic spleens of FLV-infected mice, and clone on agar. They produce tumors resembling reticulum cell sarcomas upon sc inoculation into syngeneic hosts. Stimulation of differentiation induced after treatment with dimethyl sulfoxide identifies the cells of the first line as being erythroid in origin. The two other lines are adherent and epithelioid in appearance. These lines may have originated from the nonhematopoietic cells present in fetal liver. No tumors were produced after the sc inoculation of 10⁶ cells. All three lines synthesize virus. The virus is attenuated for leukemogenicity and has no SFFV activity. The transforming event appears to be specific, because fetal liver cells from C57BL/6 mice, which are resistant to the induction of leukemia by FLV, were not affected by the virus. Malignant transformation of erythroid cells by FLV-A in vitro confirms the in vivo findings that SFFV may not be a necessary prerequisite for the induction of erythroleukemia in susceptible hosts. (27 refs)

79-2161 The State of the Globin Gene in Friend Erythroleukemia Cells. (Eng) Dube, S. K. (Sch. Medicine, Yale Univ., New Haven, CT, 06510); Wallace, R. B.; Bonner, J. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 311-317; 1978.

Friend-virus-infected cells susceptible to induction (line FSD 3) and resistant to induction (line F4+) were studied before and after induction by dimethyl sulfoxide (DMSO) to determine whether the globin gene is switched off during transformation and switched on by inducers. The DNA of the template-active fraction of induced and uninduced FSD3 cell chromatin was enriched seven-fold over whole-cell DNA for the globin gene sequence, the enrichment being essentially identical in the DNA of induced and uninduced cells. Template-active DNA from F4+ cells contained barely detectable levels of the globin gene sequence. Also, the F4+ cells did not suffer a deletion of the globin gene, as the tem-

plate-inactive DNA showed normal saturation hybridization with globin complementary DNA. The data indicate that the globin gene in Friend cells is in a transcriptionally active configuration in both induced and uninduced cells. (31 refs)

79-2162 Rosettes from Friend Leukemia Virus Envelope: Preparation and Physicochemical and Partial Biological Characterization. (Eng) Schneider, J. (Forschergruppe Tumorummunologie, Stefan-Meier-Strasse 8, D-7800 Freiburg im Breisgau, W. Germany); Schwarz, H.; Hunsmann, G. *J Virol* 29(2): 624-632; 1979.

Rosette-shaped particles containing mainly glycoprotein gp85 were isolated from the envelope of Friend leukemia virus and characterized. The isolation procedure comprised lysis of the virion by Triton X-100, affinity chromatography on concanavalin A-Sepharose, and velocity sedimentation. The rosettes displayed a mean sedimentation constant of 32S and a buoyant density of 1.21 g/ml. They contained 1% Triton X-100 and about 2% phospholipid. Gp85 was identified by polyacrylamide electrophoresis, staining with PAS reagent, and immunoprecipitation with antisera against Friend leukemia virus gp71 and p15(E). The rosettes completely blocked the cytotoxicity of the gp71 antiserum, and their ability to hemagglutinate was inhibited by antibodies to gp71. (32 refs)

79-2163 Sequential Gene Expression During Induced Differentiation of Cultured Friend Erythroleukemia Cells. (Eng) Obinata, M. (Lab. Viral Oncology, Cancer Inst., Tokyo 170, Japan); Kameji, R.; Uchiyama, Y.; Ikawa, Y. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 319-334; 1978.

Clonal cell lines derived from the T3-C1-2 Friend erythroleukemia (FE) line were used to study sequential gene expression during dimethyl sulfoxide (DMSO)-induced differentiation. Nucleic acid hybridization indicated that none of the variants of FE cells accumulated globin messenger RNA (mRNA) in the cytoplasm or nucleus in the uninduced condition and that with the addition of DMSO, globin mRNA accumulation in the cytoplasm and nucleus increased exponentially. Thus, posttranscriptional regulation was not involved in globin induction in these cells. Three frequency classes of mRNA were identified in uninduced FE cells: the first included approx 5 sequences, the second approx 400, and the last approx 9,680. Similar results were obtained in induced cells, these RNA sequences representing about 0.58% of the total unique sequences of the whole mouse genome. About 5,400-5,700 genes, representing approx 0.31%-0.34% of the mouse genome, were constitutively expressed throughout the course of differentiation; approx 3,000 genes were expressed and 4,400 were inactive during differentiation. Alteration of globin, inducible, suppressible, and common mRNA sequences was dependent on the induction of dif-

ferentiation. Only inducible messages of FE cells remained in the mouse reticulocytes; common messages disappeared during the maturation of erythroid cells. Reticulocyte non-globin messages were not expressed in FE cells. (38 refs)

- 79-2164 Genetic and Sialylation Sources of Heterogeneity of the Murine Leukemia Virus Membrane Envelope Glycoproteins gp69/71.** (Eng) Murray, M. J. (Dept. Biochemistry, Sch. Medicine, Univ. Oregon Health Sciences Center, Portland, OR, 97201); Kabat, D. J. *Biol Chem* 254(4): 1340-1348; 1979.

The heterogeneity of the membrane envelope glycoprotein of murine leukemia viruses (MuLV's) was investigated. When analyzed by polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulfate, this glycoprotein frequently separates into two components that have been termed gp69/71 because they migrate in the gels with an apparent mol wt of 69,000 and 71,000, respectively. Cloning experiments with MuLV produced by cultured Eveline cells (derived by infection of STU mouse cells with Friend MuLV) indicated that gp69 and gp71 are encoded by separate, closely related viral genomes that may frequently become incorporated into heterozygous virus particles. This and other evidence demonstrates that the size difference between gp69 and gp71 is caused by a difference in the amino acid sequences of their polypeptide chains. The gp69 and gp71 glycoproteins also have extensive isoelectric point microheterogeneity that can be reduced by removal of sialic acids with neuraminidase. Analyses of D-[³H]glucosamine-labeled glycopeptides by anion-exchange chromatography, gel filtration, and high-voltage paper electrophoresis indicated that the envelope glycoproteins are glycosylated at several sites. Apparently, the glycoproteins contain several complex oligosaccharides that are heterogeneously sialylated and at least two other relatively small neutral oligosaccharides. It is concluded that the heterogeneity of the envelope glycoprotein of MuLV's is due to at least two factors, a genetic heterogeneity caused by multiplicity of viral genomes and a variability in the numbers of sialic acid residues attached to oligosaccharides. (69 refs)

- 79-2165 Persistence and Pathogenicity of Defective Friend Spleen Focus-Forming Virus. Decreased Transplantability of Hemopoietic Cells as a Marker for Preleukemic Change.** (Eng) Eckner, R. J. (Dept. Microbiology, Boston Univ. Sch. Medicine, Boston, MA); Hettrick, K. L. *J Exp Med* 149(2): 340-357; 1979.

The oncogenic potential of purified defective Friend spleen focus-forming virus (SFFV) in mice was studied. A latent form of persistent infection was established in susceptible adults inoculated with SFFV purified free from standard leukemia-inducing helper virus (LLV-F). Initially, SFFV could be rescued directly to form splenic foci of malignant erythropoiesis in mice, but after approx 30 days, SFFV could

not be rescued after inoculation of LLV-F. This indicated that persistently infected (SFFV+) mice were either immune to exogenous helper virus or able to express SFFV-associated defective-interfering (DI) function(s). SFFV rescued by LLV-F from persistently infected normal and transformed hemopoietic cells was able to induce polycythemia in adult mice, and transplantable SFFV-induced erythroleukemic cells could be retrieved from persistently infected, histologically normal mice. The duration of SFFV persistence in normal spleen tissue suggests that the SFFV provirus resides in either a long-lived or pluripotent hemopoietic cell. Cell-surface alterations in persistently infected cells preceded the overt development of Friend leukemia and facilitated the definition of an SFFV preleukemic phase. Hemopoietic cells harboring a rescuable SFFV failed to proliferate when inoculated into lethally irradiated, syngeneic adult mice, whereas the transformed progeny of preleukemic cell populations and spleen cells transformed by the Friend virus complex (cells replicating both SFFV and LLV-F) were not rejected. Thus, histologically normal SFFV+ preleukemic cells apparently express an antigen recognition site that is not present on overtly transformed cells and that may be a pertinent surveillance target for host antileukemogenic reactions. (54 refs)

- 79-2166 The Effect of the Fv-2r Gene on Spleen Focus-forming Virus and on Embryonic Development.** (Eng) Steeves, R. A. (Dept. Genetics, Albert Einstein Coll. Medicine, Bronx, NY, 10461); Lilly, F.; Steinheid-er, G.; Blank, K. J. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 591-600; 1978.

The mechanism of the resistance to spleen focus-forming virus (SFFV) controlled by the Fv-2r gene was investigated in DBA/2 and partially congenic D2.Fv-2r and D2.Fv-1b mice. Following injection of Friend erythroleukemia virus (FV), D2.Fv-2r mice were only slightly more resistant to the expression of FV-infected cells than were D2.Fv-1b mice. This does not account for the complete resistance of D2.Fv-2r mice to spleen colony formation and is contrary to a preliminary hypothesis that the Fv-2r gene blocks malignant erythropoiesis. The possibility that the prime inhibitory effect of the Fv-2r gene could be mediated through an inhibition of SFFV replication was investigated. Spleen colony formation was shown to be an assay for infectious centers, dependent on the ability of virus released from inoculated cells to infect and replicate in adjacent cells. The principal inhibitory effect associated with the Fv-2r gene appears, therefore, to be directed against SFFV replication. Cell-mediated transfer of Fv-2r resistance was detected in two assay systems, one using a lethally irradiated host and the other Fv-1-restrictive, histocompatible F₁ hybrid recipients. In backcross experiments to produce a truly congenic strain, no Fv-2r/Fv-2r homozygotes were produced at any time during serial backcrossing to the DBA/2 strain. Thus, any gene(s) from the C57BL ancestor that might have been needed for survival of Fv-2r/Fv-2r homozygotes appeared to be lost. That such a protector gene exists and that its phenotypic expression is

dominant is demonstrated by the fact that homozygous Fv-2r/Fv-2r mice are produced normally when heterozygous DBA/2 backcross mice are mated to C57BL/6 mice. (19 refs)

- 79-2167 Immunoglobulin Synthesis by Lymphoid Cells Transformed In Vitro by Abelson Murine Leukemia Virus.** (Eng) Siden, E. J. (Dept. Biology, Center Cancer Res., Massachusetts Inst. Technology, Cambridge, MA, 02139); Baltimore, D.; Clark, D.; Rosenberg, N. E. *Cell* 16(2): 389-396; 1979.

A systematic study of immunoglobulin production by a large number of cell lines, each arising from a single focus of transformed bone marrow cells, was made. A sensitive radioimmunoprecipitation assay revealed that most cell lines derived by infection of murine bone marrow cells with Abelson murine leukemia virus (A-MuLV) synthesized a μ chain but no detectable light chain. Aside from this μ -only phenotype, lines that made only light chain, both chains, or no immunoglobulin-related polypeptides were also found. Two lines were studied in detail: one that made only μ chain and one that made only κ light chain. Synthesis of both polypeptides could be increased by modifying the culture conditions so as to decrease the growth rate of the cells. Although some κ chain secretion was observed, neither secreted nor surface μ was detected. It is suggested that the μ -only phenotype may be an early normal step in the pathway of B-lymphocyte maturation. (35 refs)

- 79-2168 Effects of Murine Leukemia Virus Infection on Differentiation of Hematopoietic Cells In Vitro.** (Eng) Teich, N. M. (Imperial Cancer Res. Fund Labs., Lincoln's Inn Fields, London WC2A 3PX, England); Dexter, T. M. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 657-670; 1978.

The interactions between murine leukemia virus (MuLV) variants and differentiating hematopoietic cells were studied in a culture system developed for long-term maintenance of murine bone marrow stem cells. Infection of marrow cultures from BDF₁ mice, which are genetically susceptible to viral erythroleukemia induction in vivo, by the Friend leukemia virus (FLV) complex changed the proliferation pattern and capabilities of the stem cells (CFU-S) and of the committed erythroid and granulocytic (CFU-C) precursor cells. Injection of syngeneic animals with infected cultured cells or with supernatants from these cultures induced erythroleukemia, showing that both the lymphatic leukemia virus (LLV) and the spleen focus-forming virus (SFFV) components of FLV replicated efficiently in the bone marrow cells. FLV-infected cultures derived from the genetically resistant C57BL mouse strain resembled uninfected control cultures. Tests of virus infectivity revealed that LLV replicated efficiently whereas SFFV did not. This suggests that the alterations in proliferative and differentiative capacity in the susceptible BDF₁ cul-

tures may be a function of SFFV expression and replication. In BDF₁ cultures infected with Moloney MuLV (MuLV-M), there was a rapid loss of CFU-S and CFU-C, suggesting that MuLV-M has a specific deleterious effect on early hematopoietic cells. Infection of BALB/c bone marrow cultures with Abelson MuLV resulted in the establishment of a transformed cell line that produced null-cell tumors in syngeneic or heterogeneic adult mice. (29 refs)

- 79-2169 Conformation of Moloney Murine Leukaemia Proviral Sequences in Chromatin from Leukaemic and Nonleukaemic Cells.** (Eng) Breindl, M. (Heinrich Pette-Institut für Experimentelle Virologie und Immunologie, Universität Hamburg, Martinistrasse 52, 2000 Hamburg 20, W. Germany); Jaenisch, R. *Nature* 277(5694): 320-322; 1979.

DNase I and micrococcal nuclease digestions were performed using chromatin from target (spleen) and nontarget (liver) cells from homozygous leukemic BALB/Mo mice. These mice carry the Moloney murine leukemia virus (M-MuLV) genome integrated into the DNA of all organs and develop a specific, thymus-derived leukemia in which expression of the M-MuLV genome is restricted to target tissues. M-MuLV-specific sequences were preferentially digested by DNase I in spleen cells but not in liver cells. However, in spleen cells in which amplification of the viral genome from one to three or four copies per haploid genome had taken place, only two of the copies were sensitive to DNase I. This suggests that the DNase I-sensitive sequences are transcriptionally active, whereas the resistant ones are inactive. Micrococcal nuclease did not preferentially digest viral sequences in target or nontarget tissues, indicating that the M-MuLV genomes in target and nontarget organs of BALB/Mo mice are organized in nucleosomal structures similar to those of the host cell DNA. Further, the data suggest that the multiple viral genome copies in tumor cells are integrated into the host cell genome and are not present as free proviral DNA. Unintegrated proviral DNA did not contribute to the DNase I-sensitive fraction of the M-MuLV-specific sequences. (17 refs)

- 79-2170 Structure of the Murine Leukemia Virus Envelope Glycoprotein Precursor.** (Eng) Witte, O. N. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139); Wirth, D. F. *J Virol* 29(2): 735-743; 1979.

The glycosylated *env* gene precursor (Pr80*env*) of Moloney murine leukemia virus was isolated by selective immunoprecipitation, and its structure was examined by treating infected NIH/3T3 cells for 3 hr with 10 or 100 μ g/ml tunicamycin. Use of the drug tunicamycin to inhibit nascent glycosylation or specific cleavage with endoglycosidase H (endo H) demonstrated that the precursor contained an apo-

protein with a mol wt of 60,000. The finished virion glycoprotein (gp70) was largely resistant to the action of endo H. Chromatography of the glycopeptides of Pr80env in conjunction with endo H digestion studies suggested that the precursor contained two distinct major glycosylation sites. Analysis of partial proteolytic cleavage fragments of Pr80env before and after endo H treatment placed the two glycosylation sites within a 30,000-dalton region of the apoprotein sequence. Kinetic experiments showed that carbohydrate processing as well as proteolytic cleavage are late steps in the maturation of Pr80env. (38 refs)

- 79-2171 Genes Controlling Receptors for Ecotropic and Xenotropic Type C Virus in *Mus cervicolor* and *Mus musculus*.** (Eng) Marshall, T. H. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014); Rapp, U. R. *J Virol* 29(2): 501-506; 1979.

Gene loci controlling cell-surface receptors for murine leukemia virus (MuLV) were studied by infecting murine x Chinese hamster hybrid cells with three C-type viruses, two ecotropic (Moloney and M813 MuLV) and one xenotropic (Mol/8155). Hybrids that exclusively segregate murine chromosomes were made by fusing *Mus cervicolor* and *Mus musculus* lymphocytes to hamster fibroblasts. Sensitivity to Moloney MuLV infection and specific binding of the envelope glycoprotein of Rauscher MuLV (gp70) cosegregated, which implies that the gp70 binding site and Moloney receptor are genetically as well as physically linked and confirms that sensitivity to MuLV infection in the hybrids is controlled by surface receptors. Isozyme analysis revealed that the gene controlling gp70 binding and Moloney MuLV infection resides on chromosome 5 in both species. With the possible exception of one clone, no evidence was found for a proviral integration site independent of chromosome 5. Evidence is presented for additional unlinked ecotropic and xenotropic receptors independent of chromosome 5. (25 refs)

- 79-2172 A Receptor-mediated Model of Viral Leukemogenesis: Hypothesis and Experiments.** (Eng) McGrath, M. S. (Lab. Experimental Oncology, Dept. Pathology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Weissman, I. L. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 577-589; 1978.

A quantitative virus-binding assay was used to investigate the frequency and specificity of murine leukemia virus (MuLV)-binding thymocytes during spontaneous AKR lymphomagenesis, in radiation-induced thymic lymphomas, and in virus-induced thymic lymphomas, in order to test the hypothesis of receptor-mediated viral leukemogenesis. Rhodaminated and fluoresceinated MuLV binding to various lymphoid cell populations was analyzed by the fluorescence-activated cell sorter to measure the frequency of cells binding either or both labeled MuLV's. Within the normal

thymus, 0.5%-3.0% of cells bore receptors for MuLV's, the majority of which appeared to be large cells. Most cells from an AKR lymphoma bound the AKR recombinant (mink cell focusing) virus MCF-247 but did not bind the Moloney murine sarcoma virus/murine leukemia virus complex [MSV(MLV)], but most cells from a Moloney lymphoma bound Moloney virus but did not bind the AKR virus. This indicates that each virus-induced lymphoma possesses receptors that can discriminate between the two viruses. In contrast, the radiation-induced lymphoma L691 bound both MCF-247 and MSV(MLV) to equally high degrees. L691 cells could be infected with MSV(MLV) and MCF-247 viruses, establishing a correlation between virus binding and virus penetration and infection. In the preleukemic period, most thymocytes produced MuLV virion proteins and expressed them as antigens; only small numbers of cells expressed MuLV receptors. Upon injection in 1-mo-old AKR mice, virus antigen-positive receptor-negative cells were not tumorigenic, whereas virus antigen-positive, receptor-positive cells were. These results support the receptor-mediated model of leukemogenesis. (13 refs)

- 79-2173 Immuno-prophylaxis and -therapy of C-Type Oncorna Viral Diseases in Mice and Cats.** (Eng) Schafer, W. (Max-Planck-Institut für Virusforschung, D-7400 Tübingen, W. Germany); Bolognesi, D. P.; de Noronha, F.; Fischinger, P. J.; Hunsmann, G.; Ihle, J. N.; Moennig, V.; Schwarz, H.; Thiel, H. J. *Med Microbiol Immunol (Berl)* 164(1/3): 217-229; 1977.

Leukemias and solid tumors caused by vertically transmitted endogenous and/or horizontally transferred exogenous C-type oncornavirus (OV's) can be significantly influenced by antiviral antibodies (ab's), particularly those against gp71. Ab's against all antigenic determinants of this viral surface component are operative in passive immunization. Thus, OV-induced tumors can be treated with a single antiserum whose success is due to combined action of the passively administered ab and an active immune response by the host. Active immunization can be achieved by immunization with gp71, but this evokes primarily type-specific responses. Active immunization can also be achieved by infection with OV followed by ab treatment. (15 refs)

- 79-2174 Rescue and Transmission of a Replication-defective Variant of Moloney Murine Leukemia Virus.** (Eng) Rein, A. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD, 20014); Benjers, B. M.; Gerwin, B. I.; Bassin, R. H.; Slocum, D. R. *J Virol* 29(2): 494-500; 1979.

The rescue and transmission of a replication-defective variant of Moloney murine leukemia virus (MuLV) from a clone of mouse cells (8A) are described. Clone 8A supernatants normally contain approx 10^2 focus-forming units/ml of murine sarcoma virus (MSV) and 10^2 complementation plaque-form-

ing units/ml of defective ecotropic MuLV; ie particles that give rise to XC plaques in assay cells simultaneously infected with XC-negative, nondefective amphotropic MuLV as well as the test virus. Superinfection of clone 8A cells with amphotropic MuLV resulted in a 500-fold increase in the titer of ecotropic MuLV particles detected in the complementation plaque assay. This increase was accompanied by a similar rise in the titer of MSV and by the production of a high level of nondefective MuLV. Rescue of defective MuLV and MSV from clone 8A showed similar kinetics, indicating that a single mechanism underlies these two phenomena. The defective MuLV rescued from clone 8A could be transmitted to a fresh clone of normal mouse cells. Amphotropic MuLV superinfection of NP-N cells, which contain a non-plaque-forming variant of N-tropic MuLV, also increased the titer of particles registering in the complementation plaque assay. Thus, NP-N cells also contain a rescuable defective variant of ecotropic MuLV. Although the assay and rescue techniques were developed through work with clone 8A, their successful application to NP-N cells indicates that they are of general utility for detecting and studying defective variants of ecotropic MuLV. (31 refs)

79-2175 The Origin, Physical Map, and Coding Properties of the Kirsten Murine Sarcoma Virus and the Friend Strain of Spleen Focus-forming Virus. (Eng) Scolnick, E. M. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD, 20014); Shih, T. Y.; Troxler, D. H.; Howk, R. S.; Young, H. A. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 535-552; 1978.

Studies of the structure, coding properties, and malignant potential of Kirsten murine sarcoma virus (Ki-MuSV), a recombinant virus derived from the Kirsten strain of murine leukemia virus (Ki-MuLV) and a replication-defective rat virus, and the Friend strain of spleen focus-forming virus (SFFV) are reviewed. The results of molecular hybridization and oligonucleotide fingerprinting indicate that Ki-MuSV has 60 nucleotides of Ki-MuLV sequences at the 5' end joined to 7,000 nucleotides of rat sequences, which, in turn, are joined to 1,000 nucleotides of Ki-MuLV sequences at the 3' end of Ki-MuSV. Thus, > 85% of Ki-MuSV is composed of rat genetic information. The malignant potential of the virus could be coded for only by the rat sequences or some combination of the rat and mouse sequences at the 3' end of the virus. A 30S RNA subunit has been identified in mouse cells that has many of the properties of the replication-defective rat virus. In in vitro translation experiments, the main proteins synthesized by Moloney murine leukemia virus RNA and Ki-MuLV RNA were a p67, a p40, and a p25. The major product synthesized with Ki-MuSV RNA and the RNA of the defective rat virus and of the defective mouse virus was a p50. SFFV was found to be a recombinant between a portion of Friend murine leukemia virus at the 5' and 3' ends with sequences related to mouse xenotropic viruses between. The xenotropic viral sequences may be responsible for the rapid leukemogenicity of SFFV. If the xenotropic se-

quences of SFFV are the 'leuk' gene, then a region of the rat sequences in Ki-MuSV might be the 'src' gene of that virus. (22 refs)

79-2176 Restriction Endonuclease Cleavage of Linear and Closed Circular Murine Leukemia Viral DNAs: Discovery of a Smaller Circular Form. (Eng) Yoshimura, F. K. (Center Cancer Res., Massachusetts Inst. Technology, Cambridge, MA, 02139); Weinberg, R. A. *Cell* 16(2): 323-332; 1979.

Both the unintegrated linear (form III) and closed circular (form I) viral DNA's obtained from JLS-V9 mouse cells infected with Moloney murine leukemia virus were cleaved by Sal I, Sma I, Bam HI, and Pst I restriction endonucleases. The resulting DNA fragments were ordered with respect to the 5' and 3' ends of the RNA genome by several techniques, including comparisons of the DNA fragments from cleavages of the linear and closed circular forms, double digestions using different combinations of enzymes, and the use of an RNA probe specific for the 3' end. DNA from Hirt extractions of infected cells yielded a discrete species of linear viral DNA whose size was determined by agarose gel electrophoresis to be 5.7×10^6 daltons. During characterization of the closed circular DNA, two form I DNA molecules were observed. The larger molecule was the same size as the linear DNA. The second molecule migrated faster on agarose gels and was the predominant species of the two closed circular DNA's. Restriction endonuclease maps show that this novel form I DNA is a smaller homogeneous species of viral DNA, missing about 600 nucleotides found in the linear and larger closed circular DNA molecules. The site of this missing DNA piece was determined to be at either one or both ends of the linear viral DNA. (35 refs)

79-2177 Oncogenic and Immunogenic Potential of Cloned HIX Virus in Mice and Cats. (Eng) Fischinger, P. J. (NCI, NIH, Building 41, Suite 400, Bethesda, MD, 20014); Ihle, J. N.; de Noronha, F.; Bolognesi, D. P. *Med Microbiol Immunol (Berl)* 164(1/3): 119-129; 1977.

HIX virus, a hybrid of the IC strain of Moloney murine leukemia virus and murine xenotropic virus (MuX), was tested for oncogenicity in newborn BALB/c and NIH Swiss mice and newborn kittens. Purified HIX virus, which had been grown in diploid cat embryo cells for three passages, induced lymphomas in both mouse strains. Only animals that had a histopathologic diagnosis of lymphoma were scored as positive. The actual incidence was probably > 50%. The same virus did not produce tumors in cats after up to 21 mo of observation. The mouse tumors were caused by HIX virus alone, because pure HIX virus was isolated from tumors without detectable eco- or xenotropic viruses. Terminal foci isolated from HIX-induced tumors in tissue culture behaved exactly as parental input virus in focus morphology,

group-specific antigens, serum factor susceptibility, and neutralization profiles. HIX may exist in BALB/c mice as an easily detectable high-titer virus, because MuX- or HIX-inactivating normal serum factor activity was reduced in tumor-bearing BALB/c mice. (19 refs)

- 79-2178 Biosynthesis of Rauscher Leukemia Virus Reverse Transcriptase and Structural Proteins: Evidence for Translational Control.** (Eng) Arlinghaus, R. B. (Dept. Biology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. & Tumor Inst., Houston, TX, 77030); Jamjoom, G. A.; Kopchick, J.; Naso, R. B. *30th Ann Symp Cancer Res* 271-295; 1978.

The possible existence of translational control over the expression of the Rauscher leukemia virus (RLV) genome was studied. Pulse-chase experiments indicated that viral precursor polypeptides are built up and processed at different rates. The chloromethyl ketone derivatives tolylsulfonyl-phenylalanyl chloromethyl ketone and carbobenzyloxyl-phenylalanyl chloromethyl ketone caused a relative enrichment of the 200,000-dalton virus-specific polypeptides (designated Pr1a+b) and a reversal of the ratio of the 80,000-dalton to the 70,000-dalton polypeptides. Pr1a+b contained determinants of both the group-specific antigens and reverse transcriptase (RT). This indicates that in RLV, the *gag* and *pol* genes are adjacent and can be translated as one polypeptide. Following pulse labeling of virus-infected cells, approx one-fifteenth as many RT sequences were made in the cell as p30 sequences, making it unlikely that the sole pathway of formation of both *gag* and *pol* gene products is by cleavage of the common precursors Pr1a+b. The formation of RT precursors appears to occur by cleavage of pre-formed Pr1a+b, whereas the formation of p30 precursors appears to follow different kinetics. With regard to the latter, an extremely fast cleavage or a nascent chain cleavage must be hypothesized. (55 refs)

- 79-2179 Influence of the Mouse Hepatitis Virus (MHV) Infection on the Growth of Human Tumors in the Athymic Mouse.** (Eng) Kyriazis, A. P. (Dept. Pathology, Univ. Cincinnati Coll. Medicine, 231 Bethesda Ave., Cincinnati, OH, 45267); DiPersio, L.; Michael, J. G.; Pesce, A. J. *Int J Cancer* 23(3): 402-409; 1979.

The growth characteristics and histologic appearance of tumors resulting from the transplantation of human tumor lines HEP-2 (laryngeal carcinoma) and SW480 (colon carcinoma) into pathogen-free and mouse hepatitis virus-infected athymic mice were studied. Sc or ip implantation of 1×10^6 neoplastic cells into pathogen-free animals resulted in tumor growth. Sc tumor transplants grew at the injection site, and they were surrounded by a capsule of connective tissue. The fibrovascular stroma supporting the neoplastic tissue was minimal, and infiltration of the tumor capsule was observed. Ip tumors

grew in a multifocal pattern, were not encapsulated, showed marked invasiveness, and metastasized. Sc tumors failed to grow in most hepatitis-infected animals that developed signs of hepatitis during the posttransplantation period, and the ip tumors did not grow at all. When larger numbers of HEP-2 tumor cells were inoculated ip, a few animals developed small, strictly localized tumor nodules with no local invasion or metastases. SW480 cells produced no tumors. No evidence supporting T-cell-mediated tumor rejection was obtained. It is concluded that the state of health of athymic mice is critical for the growth of human tumors and that it may account for the varied success in transplanting these tumors in nude mice. (21 refs)

- 79-2180 Tumor Angiogenesis Activity in Clonal Cells Transformed by Bovine Adenovirus Type 3.** (Eng) Tsukamoto, K. (Biological Res. Labs., Central Res. Div., Takeda Chemical Industries, Ltd., Osaka 532, Japan); Sugino, Y. *Cancer Res* 39(4): 1305-1309; 1979.

Four different lines of clonal cells transformed by bovine adenovirus type 3 (BAV3) and its oncogenic DNA fragments and the clonal normal counterparts of these lines were tested for tumor angiogenesis (TA) activity. TA activity was assayed by measuring the host-mediated vascular response of a chick embryo chorioallantoic membrane (CAM) to a cell suspension separated from the vascular bed by a Millipore filter. Angiogenesis activity due to an inflammation reaction of the CAM was prevented by corticosteroids. The four clonal transformed cell lines tested were TrD-5 and TrJE-6 (clonal lines of BALB 3T3 clone A31 cells transformed by the D and JE fragments of BAV3 DNA), NC1-TIC (derived from the NC1 clonal line of NIH Swiss 3T3 and transformed by BAV3), and BHK-T73 (clonal line of baby hamster kidney cells transformed by BAV3). All of the transformed cells had stronger TA activities than their clonal normal counterparts. Hepatoma B16 (solid form) sarcoma 180 (ascites and solid form), and Lewis lung tumor (solid form) also gave strong vascular responses in the TA assay. Studies with TrD-5 and A31 cells indicated that the expression of TA activity was dependent on cell dose and time. TA activity was destroyed by heating the cells. The finding of strong TA activities in TrD-5 and TrJE-6 cells, which were infected with DNA fragments that are only 16.1% and 11.9% respectively, of the BAV3 DNA, indicates that the increase in TA activity is controlled by the transforming gene of the virus. (15 refs)

- 79-2181 Humoral Antibody Response to Bovine Leukemia Virus Infection in Cattle and Sheep.** (Eng) Bex, F. (Dept. Molecular Biology, Universite Libre de Bruxelles, 67 rue des Chevaux, 1640 Rhode-St.-Genese, Belgium); Bruck, C.; Mammerickx, M.; Portetelle, D.; Ghysdael, J.; Cleuter, Y.; Leclercq, M.; Dekegel, D.; Burny, A. *Cancer Res* 39(3): 1118-1123; 1979.

Three serological methods were used to test 345 cattle from 7 herds with a history of lymphosarcoma for antibody to bovine leukemia virus (BLV) antigens. These three methods were immunodiffusion using a BLV glycoprotein with a mol wt of 60,000 (gp60) as antigen, and radioimmunoassay using a BLV gp60 and a BLV protein with a mol wt of 24,000 (p24) as antigen. The three tests gave the same results for 325 animals, with 240 being negative and 85 being positive. The results were variable in 10 cases. The gp60 antibody titers were systematically higher than the p24 antibody titers in bovine sera and milk as well as in the sera of experimentally infected sheep. In the latter case, antibodies to BLV antigens reached max values at the death of the animal in the tumor phase of the disease. Ratios of serum antiglycoprotein titer to milk titer varied between 4 and 117, showing that, if milk pools are to be used in surveys of BLV infection, use of very sensitive techniques of detection is mandatory. (39 refs)

79-2182 The Bovine Leukosis Virus. (Eng) Mussgay, M. (Federal Res. Inst. Animal Virus Diseases, Paul-Ehrlich-Strasse 28, D-7400 Tübingen, W. Germany); Dietzschold, B.; Frenzel, B.; Kaaden, O. R.; Straub, O. C.; Weiland, F. *Med Microbiol Immunol (Berl)* 164(1/3): 131-138; 1977.

The usefulness of some of the properties of bovine leukosis virus (BLV) in the serological diagnosis of enzootic bovine leukosis was determined. The properties investigated included the morphology, reverse transcriptase activity, and polypeptide pattern of BLV. The serological diagnosis of bovine enzootic leukosis may replace hematological examinations in the near future. (13 refs)

79-2183 Studies on the Polypeptides of Poxvirus. II. Comparison of Virus-induced Polypeptides in Cells Infected with Vaccinia, Cowpox and Shope Fibroma Viruses. (Eng) Ikuta, K. (Dept. Pathology, Res. Inst. Microbial Diseases, Osaka Univ., Yamada-kami, Suita, Osaka 565, Japan); Miyamoto, H.; Kato, S. *Biken J* 21(3): 77-94; 1978.

Virus-induced polypeptides (pp) in RK₁₁ cells infected with vaccinia, cowpox, and Shope fibroma viruses were examined by sodium dodecyl sulfate (SDS)-polyacrylamide gel electrophoresis followed by autoradiography. At least 42 vaccinia virus-induced pp were identified among the pp of cells pulse-labeled with [³⁵S]-methionine and/or the pp of fractionated cells labeled with [¹⁴C]-leucine for 24 hr. They consisted of 15 pp (early pp) that were able to be synthesized in the presence of cytosine-1-β-D-arabinofuranosyl HCl and 27 pp (late pp) that were synthesized only in the absence of cytosine-1-β-D-arabinofuranosyl HCl. By the same procedure, at least 40 cowpox virus-induced pp (14 early pp and 26 late pp) and at least 31 Shope fibroma virus-induced pp (13 early pp and 18 late pp) were identified. Comparative

studies of virus-induced pp on the basis of migration during SDS-polyacrylamide gel electrophoresis revealed that 11 pp were early pp common to both vaccinia and cowpox viruses; 21 were late pp common to both vaccinia and cowpox viruses; 4 were early pp common to both vaccinia and Shope fibroma viruses; 7 were late pp common to both vaccinia and Shope fibroma viruses; 5 were early pp common to both cowpox and Shope fibroma viruses; 9 were late pp common to both cowpox and Shope fibroma viruses; 4 were early pp common to all three viruses; and 7 were late pp common to all three viruses. (17 refs)

79-2184 Vaccinia Virus Replication. I. Requirement for the Host-Cell Nucleus. (Eng) Hruby, D. E. (Dept. Microbiology, Health Sciences Center, State Univ. New York, Stony Brook, NY, 11594); Guarino, L. A.; Kates, J. R. *J Virol* 29(2): 705-715; 1979.

The ability of vaccinia virus (VV) to replicate in the absence of the host-cell nucleus was examined in several mammalian cell lines by cytochalasin B-induced enucleation techniques. Virus-infected enucleated cells (cytoplasts) prepared from BSC-40, CVC, and L cells were incapable of producing infectious progeny virus. The nature of this apparent nuclear involvement was studied in detail in BSC-40 cells. Modulations designed to maximize cytoplasmic integrity and longevity, such as reduction of the growth temperature and initial multiplicity of infection, did not improve virus growth in cytoplasts. Sodium dodecyl sulfate-polyacrylamide gel analysis of the [³⁵S]methionine pulse-labeled proteins synthesized in VV-infected cytoplasts demonstrated that both early and late viral gene products were being expressed at high levels and with the proper temporal sequence. VV cytoplasmic DNA synthesis, as measured by [³H]thymidine incorporation, peaked at 3 hr postinfection and was 70%-90% of control levels in cytoplasts. However, in the cytoplasts this DNA was not converted to a DNase-resistant form late in infection, which was consistent with the failure to isolate physical particles from infected cytoplasts. Treatment of VV-infected cells with 100 μg of rifampin/ml from 0 to 8 hr postinfection to increase the pools of viral precursors, followed by subsequent removal of the drug, resulted in a threefold increase in virus yield. This treatment had no effect on virus-infected cytoplasts. Finally, VV morphogenesis was studied under an electron microscope in thin sections of virus-infected cells and cytoplasts that had been prepared at various times during a single-step growth cycle. It was apparent that, although early virus morphogenetic forms appeared, there was no subsequent DNA condensation or particle maturation in the cytoplasts. These results suggest that VV requires some factor or function from the host-cell nucleus in order to mature properly and produce infectious progeny virus. (29 refs)

79-2185 Feline Sarcoma Virus-coded Polypeptide: Enzymatic Cleavage by a Type C Virus-coded

Structural Protein. (Eng) Khan, A. S. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Stephenson, J. R. *J Virol* 29(2): 649-656; 1979.

A purified 15,000-dalton (15K) Prague strain Rous sarcoma virus *gag* gene-coded structural protein, p15, was shown to enzymatically cleave the previously described 130K feline sarcoma virus (FeSV)-coded precursor polyprotein Pr130. Cleavage products included proteins ranging in mol wt from 12K to 110K. The specificity of this cleavage reactivity was indicated by the fact that, under similar conditions, neither purified C-type viral structural proteins nor nonviral proteins such as bovine serum albumin were cleaved to significant extents. Moreover, the feline leukemia virus *gag* gene-coded precursor polyprotein Pr65*gag* was efficiently cleaved, resulting in the generation of proteins of 30K (p30), 15K (p15), 12K (p12), and 10K (p10). Using enzymatically (p15) treated FeSV Pr130 as starting material, a major 72K cleavage product was purified and shown to contain the nonstructural component of FeSV Pr130. (22 refs)

79-2186 Immunosuppressive Properties of a Virion Polypeptide, a 15,000-Dalton Protein, from Feline Leukemia Virus. (Eng) Mathes, L. E. (Dept. Veterinary Pathobiology, Coll. Veterinary Medicine, Ohio State Univ., Columbus, OH, 43210); Olsen, R. G.; Hebebrand, L. C.; Hoover, E. A.; Schaller, J. P.; Adams, P. W.; Nichols, W. S. *Cancer Res* 39(3): 950-955; 1979.

Inactivated whole feline leukemia virus (FeLV) and subviral components of FeLV were analyzed for their inhibitory effect on concanavalin A (ConA)-stimulated lymphocyte blast transformation (LBT) using lymphocytes from specific pathogen-free cats. Inactivated FeLV inhibited LBT by 43% and a subfraction containing a 15,000-mol-wt peptide (p15) as its major component inhibited it by 41%; three other protein subfractions had no significant effects. Purified p15 inhibited LBT by 68%, but purified p27 inhibited it by only 18%. The inhibition was apparently not due to p15 cytotoxicity or to competition for Con A-binding sites. FeLV and FeLV p15 caused alterations in cell membrane function, as indicated by an up to 83% inhibition of the normal capping process. Cats inoculated with heat-killed FL-74 cells were protected from feline sarcoma virus (FeSV) challenge, but when p15 was added to the FL-74 cell vaccine, the incidence of progressive fibrosarcoma was significantly increased after FeSV challenge. The data support the hypothesis that the immunosuppression observed in cats infected with FeLV is mediated by FeLV p15. (25 refs)

79-2187 Feline Oncornavirus-associated Cell-Membrane Antigen: An FeLV- and FeSV-induced Tumor-specific Antigen. (Eng) Hardy, W. D. (Lab. Veterinary Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Zuckerman, E. E.; Essex, M.; MacEwen,

E. G.; Hayes, A. A. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 601-623; 1978.

The cell membranes of naturally occurring pet cat tumors and normal cat cells were tested for feline oncornavirus-associated cell-membrane antigen (FOCMA) to determine if it is unique to feline leukemia virus (FeLV)- and feline sarcoma virus (FeSV)-induced cat tumors. Of the 44 cats studied, 31 were infected with FeLV, whereas 13 were nonproducers. Twenty-seven cats had T-cell lymphosarcomas (LSA's), 6 B-cell LSA's, 10 mixed-cell LSA's, and 1 a null-cell LSA. Every LSA cell preparation tested had FOCMA in the cell membrane whether or not the LSA cells were replicating FeLV or were nonproducers. FOCMA was absent from the cell membranes of morphologically normal peripheral blood lymphocytes obtained from four of the FeLV-infected cats with LSA's and from five of the nonproducer cats with LSA's. Eight nonlymphoid cat tumors tested for FOCMA were negative, but granulocytic tumor cells from an FeLV-infected cat with myelogenous leukemia, tumor cells from an FeLV-infected cat with megakaryocytic leukemia, two fibrosarcoma cultures derived from cats with naturally occurring FeSV-induced fibrosarcomas, and a canine nonproducer sarcoma cell culture derived from a puppy with FeSV-induced sarcoma were all FOCMA-positive. FOCMA was not detected on any normal cells, even if they were actively producing FeLV. These studies have directly established that FOCMA is expressed only on cat cells transformed by FeLV or FeSV. The finding that FOCMA is expressed on granulocytic and megakaryocytic leukemic feline cells suggests that FeLV can transform cells other than lymphoid cells. (72 refs)

79-2188 Mobility of Lymphocyte Surface Membrane Concanavalin A Receptors of Normal and Feline Leukemia Virus-infected Viremic Felines. (Eng) Dunlap, J. E. (Dept. Pathology, Ohio State Univ., Columbus, OH, 43210); Nichols, W. S.; Hebebrand, L. C.; Mathes, L. E.; Olsen, R. G. *Cancer Res* 39(2): 956-958; 1979.

The virus-associated depression of concanavalin A (Con A) mitogenesis that accompanies feline leukemia virus (FeLV)-induced cat lymphoma was investigated by comparing the lymphocyte surface receptor mobility of normal cats to that of viremic diseased animals. The mechanics of feline lymphocyte receptor mobility were studied using fluorescein-conjugated Con A to quantitate lymphocyte capping. The results of a study of 21 disease-free animals showed that cat lymphocytes undergo appreciable Con A capping, with a mean capping rate of 17% under conditions developed in this study. In contrast, morphologically normal peripheral blood lymphocytes of six FeLV-infected viremic cats, with or without lymphoma, exhibited a mean capping rate of only 7%, significantly less than that of the control animals ($p < 0.005$). These findings suggest that a membrane-related lymphocyte deficiency accompanies the development of virus-induced lymphoma in the cat. (35 refs)

79-2189 Infection and Immunization of Cats with the Kawakami-Theilen Strain of Feline Leukemia Virus. (Eng) Salerno, R. A. (Div. Virus and Cell Biology Res., Merck Inst. Therapeutic Res., West Point, PA, 19486); Larson, V. M.; Phelps, A. H.; Hilleman, M. R. *Proc Soc Exp Biol Med* 160(1): 18-23; 1979.

The effects of viral dose, mode of transmission, and host age on the responses of specific-pathogen-free cats to the Kawakami-Theilen strain of feline leukemia virus (KT-FeLV) were studied. Injections of high doses of KT-FeLV (10^9 - 10^{12} virions) into 29 1- to 2-day-old kittens resulted in illness in 13. The sick kittens became moribund and showed other evidence of disease; FeLV was isolated from the peripheral blood lymphocytes of these, but not the healthy, kittens. Cytotoxic antibody against FeLV-infected FL74 feline lymphoid tumor cells developed in 10/16 non-viremic inoculated kittens, 6/15 nonviremic cats in contact with viremic kittens, and 0/13 viremic kittens. None of a group of 17- to 24-wk old cats became ill or developed viremia when inoculated with high doses of KT-FeLV, but nearly all developed cytotoxic antibody. In neither experiment did animals in contact with the inoculated cats become ill or develop viremia. Two cats were given six doses of formalinized FeLV vaccine im. One developed both neutralizing and cytotoxic antibody titers, and the other developed a cytotoxic antibody titer. The incidence of leukemia was 20% among the five offspring of these cats following challenge with KT-FeLV; the incidence of leukemia among eight kittens from unvaccinated queens was 88% following challenge. (25 refs)

79-2190 Human Humoral Antibodies Specific for Primate C-Type Viral Antigens. (Eng) Kurth, R. (Friedrich Miescher-Laboratorium der Max Planck-Gesellschaft, Spemannstrasse 37-39, D-7400 Tübingen, W. Germany); Schmitt, C. *Med Microbiol Immunol (Berl)* 164(1/3): 167-177; 1977.

Human sera were examined for the presence of natural antibodies directed against antigenic determinants of C-type virus structural proteins. Iodinated proteins from detergent-disrupted baboon endogenous virus (BEV) and replication-defective simian sarcoma virus (simian sarcoma-associated helper virus) [SSV(SSAV)] were used as antigens. The immune reactions appeared to be specific for virus antigens. Approx 50% of >100 normal sera tested recognized SSV(SSAV) antigens, and about 80% of the sera recognized BEV antigens. Individual sera precipitated one, two, or all three of the virus structural proteins p28, gp70, or p15. The immune reaction was mediated by human IgG, and preliminary experiments showed that IgM might also be involved. There was no immunological evidence that vertical virus transmission or active vertical antiviral immunization occurred. However, antiviral maternal IgG was transmitted into cord blood. (33 refs)

79-2191 A New Virion Precipitation Test for Oncovirus Envelope Antigens Which Detects Common Antigenic Determinants in Mammalian Type-C Viruses and Mason-Pfizer Monkey Virus. (Eng) Altstein, A. D. (D. I. Ivanovsky Inst. Virology, USSR Acad. Medical Sciences, Moscow, USSR); Zakharova, L. G.; Zhdanov, V. M. *Int J Cancer* 23(3): 424-433; 1979.

The virion precipitation test (VPT) was developed for the study of oncovirus (OV) envelope antigens based on the precipitation of intact virions by a double-antibody technique. The amount of precipitated virus was then determined by measuring its reverse transcriptase activity. Internal antigens of the virions were not precipitated. The method was used to study the relationship between the envelope antigens of 11 different OV's. Four groups of OV's having no cross-relationships in their envelope antigens were distinguished: mammalian C-type viruses and Mason-Pfizer monkey virus (M-PMV); murine B-type virus (mouse mammary tumor virus); bovine leukemia virus; and avian C-type viruses (Prague strain of Rous sarcoma virus). Within the first group, VPT demonstrated a broad cross-relationship. The following subgroups were distinguished within the group of mammalian C- and D-type viruses: murine C-type viruses, feline leukemia virus; endogenous feline C-type virus RD-114 and endogenous baboon C-type virus BK-CT, simian sarcoma virus, and M-PMV. Antibodies that reacted with the common determinants could not be removed by absorption with human cells and normal calf serum. This cross-reactivity could be selectively removed by absorption of the sera with the viruses. The common antigenic determinants may provide significant information concerning OV evolution. (22 refs)

79-2192 Mason-Pfizer Like Virus in Kidney Grafted Patients. (Eng) Thiry, L. (Institut Pasteur du Brabant, 1040 Brussels, Belgium); Sprecher-Goldberger, S.; Vandebussche, P.; Bossens, M.; Vereerstraten, P.; Hestermans-Medard, O. *Med Microbiol Immunol (Berl)* 165(4): 255-269; 1979.

Lymphocytes from kidney-graft patient were specifically stimulated to incorporate thymidine in vitro by mitomycin C-treated HeLa cells infected with a Mason-Pfizer-like virus (MPV). The thermolabile mutant of vesicular stomatitis virus (VSV tl) grown in the WBC of this patient produced pseudotypes that were neutralized by the patient's sera and by rabbit anti-MPV sera. Coculture of the patient's WBC with rabbit cornea cells (SIRC) yielded virus populations with dual properties: those of MPV plus those of another virus that was not typed serologically but possessed the biological properties of typical C particles. These virus populations were characterized by reverse transcriptase activity in the presence of Mn^{2+} and Mg^{2+} as well as by syncytium formation on both XC cells (rat cells with Rous genes) and KC cells (human cells carrying the Rous genome). The patient also had neutralizing antibodies to MPV, which were detected by inhibition of syncytium formation on KC cells and by neutraliza-

tion of the VSV tl (MPV) pseudotypes. These pseudotypes, which were obtained from two WBC cultures of the same patient, were not obtained with 18 other graft patients or with 13 healthy adults. MPV-like viruses could be latent in graft patients and activated by immunosuppressive drugs, or they may be introduced in the patients by the kidney graft or by the repeated blood transfusions. (38 refs)

- 79-2193 Transformation of Hamster Kidney Cells by Simian Papovavirus SA12.** (Eng) Valis, J. D. (Dept. Pathobiology, Johns Hopkins Univ. Sch. Hygiene and Public Health, Baltimore, MD, 21205); Strandberg, J. D.; Shah, K. V. *Proc Soc Exp Biol Med* 160(2): 208-212; 1979.

The transformation of hamster kidney (HK) cells by simian agent 12 (SA12 virus) was studied, as was the ability of transformed cells to produce tumors in syngeneic hosts. HK cells inoculated with SA12 showed transformation characterized by increased saturation density, altered morphology, loss of contact inhibition, increased growth rate, an indefinite life-span, reduced serum requirements for growth, an ability to grow in soft agar, and the presence of SA12-specific tumor (T) antigen. Neither infectious virus nor viral structural antigen was demonstrated by Sendai virus-induced fusion of transformed HK (SAHK-1) cells with permissive cells. SAHK-1 cells inoculated into weanling hamsters consistently produced tumors that were readily maintained by passage in hamsters. The cells appeared to become more tumorigenic after successive passage in hamsters. Pure adenocarcinomas, undifferentiated sarcomas, and mixed tumors containing both carcinomatous and sarcomatous elements were seen. SA12 T antibodies were detected in each of 16 sera from individual tumor-bearing hamsters. (9 refs)

- 79-2194 Detection of Herpes Simplex Virus Tumor-associated Antigen in Uterine Cervical Cancer Tissue. Five Case Studies.** (Eng) Notter, M. F. (Dept. Microbiology and Cell Biology, Pennsylvania State Univ., 101 S. Frear Bldg., University Park, PA, 16802); Docherty, J. J.; Mortel, R.; Hollinshead, A. C. *Gynecol Oncol* 6(6): 574-581; 1978.

Biopsy specimens from five patients with gynecologic cancers were examined for the presence of herpes simplex virus tumor-associated antigen (HSV-TAA) using the peroxidase-antiperoxidase technique. The first patient, who had a squamous carcinoma confined to the uterine cervix, was negative for HSV-TAA when tested with rabbit anti-HSV-TAA, but was positive when tested by complement fixation. The second and third patients had tumor extending beyond the cervix but without parametrial involvement. Serologic and immunoenzymatic evaluations showed the second patient to be positive for HSV-TAA and the third patient to be negative. The fourth patient showed obvious parametrial involvement. This patient was positive for HSV-TAA when

tested immunoenzymatically or serologically, but was negative when tested with nonimmune rabbit serum. The fifth patient had adenoacanthoma and lacked antibodies to HSV-TAA. However, sera from all five patients reacted with antigens of HSV types 1 and 2 in the complement-fixation test. The data suggest a role for HSV in certain gynecologic cancers. (12 refs)

- 79-2195 Anatomy of Herpes Simplex Virus DNA. XI. Apparent Clustering of Functions Effecting Rapid Inhibition of Host DNA and Protein Synthesis.** (Eng) Fenwick, M. (Dunn Sch. Pathology, Oxford, England); Morse, L. S.; Roizman, B. *J Virol* 29(2): 825-827; 1979.

The suppression of host protein and DNA synthesis was measured in confluent monolayers of Vero cells infected with herpes simplex virus type 1 (HSV-1), HSV-2, or several intertypic recombinants. The simple technique used is based on the observation that rapid suppression of host synthesis by HSV-2 does not require detectable viral protein or DNA synthesis. Therefore, cells were either (1) infected in the presence of actinomycin D to prevent transcription of viral messenger RNA, and the rate of incorporation of ¹⁴C-amino acids into acid-precipitable material was measured 1.5 hr later; (2) infected with UV light-irradiated virus, and the rate of incorporation of ³H-thymidine was measured 1.5 hr later. The three HSV-2 strains tested inhibited the synthesis of both DNA and protein of the host cell more rapidly than three HSV-1 strains. The HSV-2 strains also caused substantially greater suppression of DNA and protein synthesis than the HSV-1 strains. The two synthesis functions cosegregated in all eight recombinants tested and are therefore controlled by the same gene or by different genes in the same region of the viral DNA. By examining the crossover sites in the DNA's of three recombinants, it was concluded that the gene or genes whose products effect the rapid inhibition of host DNA and protein synthesis lie in the region between 0.52 and 0.59 map units. (9 refs)

- 79-2196 In Vitro Acquisition of Resistance Against Herpes Simplex Virus by Permissive Murine Macrophages.** (Eng) Sethi, K. K. (Institut Medizinische Mikrobiologie und Immunologie, Universitat Bonn, D-5300 Bonn-Venusberg, W. Germany); Brandis, H. *Arch Virol* 59(3): 157-172; 1979.

The ability of peritoneal macrophages (PM) from adult mice to support the productive replication of herpes simplex virus (HSV) types 1 and 2 was studied. PM cultures prepared from adult mice of strains DBA/2J, AKR, and BALB/c supported the replication of infectious HSV-1 and -2. The yield of HSV was significantly higher in cultures of simian virus 40-transformed C57BL/6J PM than in normal PM, and PM from HSV- or Listeria-immunized DBA/2J mice effectively inhibited the replication of test HSV relative to PM from nonim-

mune mice. Supernatant fluids from 72-hr-old mixed lymphocyte cultures (MLC) induced adult DBA/2J and suckling C57BL/6J PM to restrict HSV replication. These macrophages could also inhibit HSV replication if pretreated with the supernatant from cultures of specific-antigen-stimulated HSV- or *Listeria*-immune spleen lymphocytes (SL) or the supernatant from concanavalin A-stimulated SL. Sensitized T cells were essential for the generation of active supernatants. The supernatant from MLC or antigen-stimulated *Listeria*- or HSV-immune SL inhibited mouse, but not hamster or chick, embryo cells. The active factor(s) in the supernatant fluids was not sensitive to heating or exposure to ribonuclease or deoxyribonuclease, but it was inactivated by exposure to hydrochloric acid (pH 2) or trypsin. (34 refs)

- 79-2197 Molecular Genetics of Herpes Simplex Virus. II. Mapping of the Major Viral Glycoproteins and of the Genetic Loci Specifying the Social Behavior of Infected Cells.** (Eng) Ruyechan, W. T. (Dept. Biochemistry, Uniformed Services Univ. Health Sciences, Bethesda, MD, 20014); Morse, L. S.; Knipe, D. M.; Roizman, B. *J Virol* 29(2): 677-697; 1979.

The location in herpes simplex virus (HSV) DNA of the templates specifying the major viral glycoproteins (gp's) and of mutations causing alterations in the social behavior of infected cells, ie, clumping of rounded cells and polykaryocytosis, was mapped. Analysis of HSV-1 x HSV-2 recombinants showed that sequences encoding the gp VP19E map in the S component of the DNA between map units 0.90 and 0.945, whereas sequences encoding the gp's VP8.0, VP7, and VP8.5 are in two locations in the L component of HSV DNA. Apparently, the templates specifying the HSV-1 and HSV-2 gp VP8.0 were not colinear. HSV-1 gp VP8.0 mapped between 0.53 and 0.645 map units, HSV-2 gp VP8.0 between 0.645 and 0.69 map units. The templates specifying gp's VP8.5 and VP7 may be closely linked and colinear in HSV-1 and HSV-2 DNA's; they map between 0.30 and 0.42 map units on the HSV DNA. Marker transfer experiments involving transfection of rabbit skin cells with donor HSV-1 DNA and fragments from several donor strains causing fusion of Vero and/or HEp-2 cells revealed the existence of three *syn* loci specifying the social behavior of cells and one locus (*Cr*) determining the accumulation of gp VP8.0. The *Cr* locus maps to the right of the template specifying gp VP8.0. Loci *syn* 1 and *syn* 2 map at or near the *Cr* locus but can be segregated from it. Locus *syn* 3 maps at or near the template specifying gp's VP7 and VP8.5. The expression of mutations in the *syn* 1 and *syn* 3 loci appears to be cell-type-dependent; the cell-type dependence of the *syn* 2 locus is not clear. (60 refs)

- 79-2198 Polyamine Metabolism in MRC5 Cells Infected with Different Herpesviruses.** (Eng) Tyms, A. S. (Dept. Virology, St. Mary's Hosp. Medical Sch., Paddington, London W2 1PG, England); Scamans, E.; Williamson, J. D. *Biochem Biophys Res Commun* 86(2): 312-318; 1979.

The effect of inhibitors of polyamine metabolism on the replication of herpes simplex virus types 1 and 2 (HSV-1 and HSV-2) and human cytomegalovirus (HCMV) was studied in MRC-5 human diploid fibroblasts. Both methylglyoxal bis(guanyldiazide), an inhibitor of S-adenosyl-L-methionine decarboxylase, and DL- α -methylornithine, an inhibitor of ornithine decarboxylase, were potent inhibitors of the replication of HCMV in MRC-5 cells. These compounds did not affect the replication of HSV-1 or HSV-2. This difference in antiviral effect was related to the stimulation of spermidine and spermine synthesis in host cells following HCMV infection and the inhibition of polyamine metabolism in HSV-1- or HSV-2-infected cells. Inhibition of HCMV replication by the polyamine biosynthesis inhibitors was accompanied by a marked decrease in the formation of intranuclear, DNA-containing inclusions characteristic of HCMV infection. These results suggest that there are significant differences in the replication mechanisms of different herpesviruses. (18 refs)

- 79-2199 Molecular Genetics of Herpes Simplex Virus. III. Fine Mapping of a Genetic Locus Determining Resistance to Phosphonoacetate by Two Methods of Marker Transfer.** (Eng) Knipe, D. M. (Marjorie B. Kovler Viral Oncology Labs., Univ. Chicago, Chicago, IL, 60637); Ruyechan, W. T.; Roizman, B. *J Virol* 29(2): 698-704; 1979.

A genetic locus determining resistance to phosphonoacetic acid (*PAAr*) was transferred from one herpes simplex virus (HSV) genome to another by two methods of marker transfer. In one method, rabbit skin cells were transfected with mixtures consisting of intact DNA extracted from HSV-1 *PAAr* viral capsids and an individual restriction endonuclease DNA fragment generated from HSV-1 *PAAr* DNA. The other method involved transfection of rabbit skin cells with intact HSV-1 *PAAr* DNA and an individual restriction endonuclease fragment generated by digestion of HSV-1 *PAAr* DNA; the mixture had been denatured and reannealed for various periods of time. Both methods yielded viral progeny resistant to PAA. These two methods mapped the *PAAr* locus between positions 0.45 and 0.53 map units on the physical map of the viral DNA. Fine mapping of the *PAAr* locus showed that it maps at or near an *EcoRI* restriction endonuclease site at either 0.46 or 0.49 map units. Using the first method of marker transfer, which depended on recombination in the infected cell between an intact genome and a restriction endonuclease fragment bearing the genetic marker, yields of as much as 10% of the viral progeny bore the marker introduced on the DNA fragment. In the second method, which required repair of a partial heteroduplex formed between intact DNA and a restriction endonuclease fragment bearing the genetic marker, a yield of 35% *PAAr* progeny was achieved using a 1.5-fold excess of fragments. (29 refs)

- 79-2200 Anatomy of Herpes Simplex Virus DNA. XII. Accumulation of Head-to-Tail Concatemers in Nuclei of Infected Cells and Their Role in the Generation of the Four Isomeric Arrangements of Viral DNA.** (Eng) Jacob, R. J. (Marjorie B. Kovler Viral Oncology Lab., Univ. Chicago, Chicago, IL, 60637); Morse, L. S.; Roizman, B. *J Virol* 29(2): 448-457; 1979.

Herpes simplex virus type 1 DNA extracted from virions accumulating in the cytoplasm of infected cells has previously been shown to consist of four populations of linear molecules differing in the orientation of the covalently linked large (L) and small (S) components relative to each other. Together, these four isomeric arrangements of viral DNA display four different termini and four different L-S component junctions. Restriction endonucleases were used to analyze newly replicated viral DNA shortly after the onset of viral DNA synthesis, progeny DNA accumulating in the nuclei late in infection, and rapidly sedimenting DNA present in nuclei of infected cells at 8 hr after infection. In each instance, the nuclear viral DNA contained a decreased concentration of all four terminal fragments and an increased concentration of fragments spanning the junction of L and S components relative to the concentration of other DNA fragments. The results are consistent with the hypothesis that the viral DNA accumulating in the nuclei consists of head-to-tail concatemers arising from the replication of DNA by a rolling-circle mechanism. A model is presented for the generation of all four isomeric arrangements of herpes simplex virus DNA from one arrangement based on excision and repair of unit length DNA from head-to-tail concatemers and on known features of the sequence arrangement of viral DNA. (29 refs)

- 79-2201 Infection of Avian Lymphoblastoid Cell Lines with Type 2 Herpes Simplex Virus.** (Eng) Nii, S. (Dept. Virology, Okayama Univ. Medical Sch., Shikatacho, Okayama 700, Japan); Arita, K.; Asai, T. *Biken J* 21(3): 115-119; 1978.

The susceptibility of the avian lymphoblastoid cell lines 1104 X-5 and MSB-1 to infection with herpes simplex virus type 2 (HSV-2) was examined by electron microscopy and by the fluorescent antibody technique. MSB-1 cells were infected at an input multiplicity of 4 and 1104 X-5 cells at a multiplicity of 5. At 32 hr after infection, herpes-type virus particles could be seen in a few 1104 X-5 cells. Extracellular particles of HSV occasionally coexisted with C-type particles. At 15 hr after infection, approx 2%-3% of MSB-1 cells contained herpes-type virus. Most virus-infected nuclei contained capsids with a low-density core that was 40 nanometers in diameter. Microtubules, which are characteristic of HSV infection, were also seen in the nuclei of HSV-2 infected MSB-1 cells. In fluorescent antibody studies, the antigen began to appear 4 hr after infection, and the percentage of antigen-positive cells increased as infection proceeded. However, the max percentage reached was 20% in 1104 X-5 cells at 9 hr and 9% in MSB-1 cells at 10 hr. These results indicate that the two

avian lymphoblastoid cell lines are fairly susceptible to a human herpesvirus, but it is not known why most cells of both lines were so resistant to HSV-2 infection even when exposed to a high dose of the virus. (9 refs)

- 79-2202 Enhancement of Biochemical Transformation of Mammalian Cells by Herpes Simplex Virus Following Nitrosomethylurea Treatment.** (Eng) Howett, M. K. (Dept. Microbiology, Milton S. Hershey Medical Center, Hershey, PA, 17033); Pegg, A. E.; Rapp, F. *Cancer Res* 39(3): 1041-1045; 1979.

A quantitative assay for the biochemical transformation of thymidine kinase-deficient mouse cells (N cIA cl10) to an enzyme-positive phenotype by herpes simplex virus type 2 (HSV) was used to study the effects of a noncytotoxic concentration (0.04 mM) of nitrosomethylurea (NMU) on cell transformation. Transformation was enhanced in cells treated with NMU 24 hr after exposure to HSV compared with untreated virus-exposed cells. The enhancement in susceptibility to transformation disappeared when 72 hr elapsed between virus exposure and NMU treatment. By 72 hr after infection, > 90% of the 7-methylguanine and more than 75% of the O⁶-methylguanine were removed from the cell DNA. At 24 hr postinfection, however, less of the damage had been repaired, and enzymatic excision and repair were actively occurring. Thus, enhanced susceptibility to transformation coincided with the presence of alkylated bases and/or ongoing repair. HSV infection did not alter the ability of the cells to repair NMU damage. (41 refs)

- 79-2203 Transfer of the Herpes Simplex Thymidine Kinase Gene from Human Cells to Mouse Cells by Means of Metaphase Chromosomes.** (Eng) Sabourin, D. J. (Div. Human Genetics, Children's Hosp. Medical Center, Harvard Medical Sch., Boston, MA, 02115); Davidson, R. L. *Somatic Cell Genet* 5(2): 159-174; 1979.

To test for the integration of the herpes simplex virus (HSV) thymidine kinase (TK) gene into the chromosomes of HSV-transformed human cells, the latter were isolated following exposure of TK-deficient human cells to UV-inactivated HSV type 1 and selection in HAT medium. The transformed human cells produced TK with the electrophoretic characteristics of the activity appearing in cells lytically infected with HSV-1. Next, metaphase chromosomes were purified from the transformed human cells and incubated with TK-deficient mouse cells. Several presumptive herpes gene transferents of independent origin were isolated, and three were characterized in detail. All three lines expressed herpes TK activity rather than mouse or human TK. The gene transferents contained no intact human chromosomes. When removed from selective pressure, they rapidly lost the TK⁺ phenotype. However, upon continued growth in nonselective medium, a subpopulation in which the TK⁺ pheno-

type had become more stabilized appeared. The results indicate that the herpes TK gene was integrated into the genome of the HSV-transformed human cells and that its transfer to the TK-deficient mouse cells was mediated by metaphase chromosomes. (32 refs)

- 79-2204 Replication of Herpes Simplex Virus Type 2 in Normal Dysplastic and Neoplastic Human Cervical Epithelia.** (Eng) Mandeville, R. (Institut du Cancer de Montreal, Centre Hospitalier Notre Dame, 1560 Sherbrooke est, Montreal, Canada H2L 4M1); Holloway, A.; Laughlan, S. C.; Simard, R. *Eur J Cancer* 5(3): 351-361; 1979.

The organ culture method was used to determine the response of cultured human cervical epithelium explants to herpes simplex type 2 (HSV-2) infection. Biopsied cervical epithelium from 30 patients with cervical dysplasia, 15 with cervical carcinoma in situ (CIS), 20 with cervical invasive cancer, and 185 normal subjects was used. The cultured cells resembled their in vivo counterparts morphologically. As shown by (³H)-thymidine labeling, proliferative cells were confined to the parabasal and basal layers of the squamous epithelium in the normal preparations. In the dysplastic and neoplastic tissues, labeling of cells in the superficial zone reflected disturbances in the rate of DNA replication. Within 4 days after HSV-2 infection, 70% of the epithelial cells from the normal preparations showed cytopathological changes characteristic of virus transformation. The explants derived from cervical dysplasias showed the same changes in response to HSV-2 infection, but they showed them 1 to 2 days earlier than the normal tissues. The CIS and invasive cancer explants responded in an identical manner, but they also showed the presence of large numbers of polykaryocytes postinfection that were not present in the transformed dysplastic or normal preparations. Virus particles were found in all infected explants 72 hr postinfection, and the virus titer remained high at 96 hr postinfection, reaching values of 9.5×10^1 plaque-forming units/ml. The amount of infective virus always decreased significantly later in the course of infection. (24 refs)

- 79-2205 Uninhibited Growth and Metastases of Herpes Simplex Virus-Transformed Cells in Virus-sensitized Hosts.** (Eng) Hay, K. A. (Dept. Microbiology and Specialized Cancer Res. Center, Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA, 17033); Lausch, R. N. *Int J Cancer* 23(3): 337-343; 1979.

Four established lines of hamster cells transformed by herpes simplex virus type 1 or 2 (HSV-1 and HSV-2) that were not shedding the virus were examined for continued expression of virus-associated antigens. Sera collected from hamsters bearing HSV isografts showed a generally low incidence of neutralizing activity against HSV-1 and HSV-2, suggesting that only small quantities of virion antigen were present in

the cells. Hyperimmunization studies in rabbits supported this explanation. Repeated immunization of rabbits with tumor cells in Freund's complete adjuvant resulted in the production of specific virus-neutralizing antibody. Hamsters sensitized to HSV and resistant to virulent virus challenge did not reject low numbers of tumor cells, and the incidence of lung metastases was not significantly reduced. Cervical lymph node cells from hamsters immunized with HSV-1 were significantly cytotoxic for virus-infected hamster embryo fibroblasts, but they did not lyse any of the HSV-1- or HSV-2-transformed cell lines tested. Studies with tumor cell-sensitized hamsters indicated that the HSV-transformed lines were at most only weakly immunogenic and/or immunosensitive in syngeneic hosts. Animals immunized with HSV-1 plus HSV-1-transformed tumor cells were as resistant to tumor cell challenge as hosts immunized to tumor cells only. The data indicate that the HSV tumor lines expressed low levels of virus structural antigens but not virus-specific transplantation-rejection antigen. (25 refs)

- 79-2206 Proliferation of Hamster Embryo Fibroblast Cultures Infected with Herpes Simplex Virus.**

(Rus) Ageenko, A. I. (Lab. Virology, P. A. Hertsen Res. Oncological Inst., Moscow, USSR); Kogan, I. Ia. *Vopr Onkol* 25(2): 39-42; 1979.

To determine whether human herpes simplex virus type 2 can stimulate DNA synthesis in both permissive and nonpermissive systems, hamster embryo fibroblast (HEF) cultures were infected with the virus prior to monolayer formation and then incubated in medium containing ³H-thymidine. The labeling index started to increase within the first hours of infection, and it reached a max after approx 15 hr. At 72 hr, the labeling index was 8%, compared with 2% in control cultures. Infection of HEF during the stationary phase also increased proliferative activity: 72 hr after infection, the labeling index was 5%-6%, compared with 1%-2% in control cultures. (9 refs)

- 79-2207 Transformation of Hamster Embryonic Fibroblast Cells by UV-Irradiated Human Cytomegalovirus.** (Eng) Boldogh, I. (Inst. Microbiology, Univ. Medical Sch., H-4012 Debrecen, P.O.B. 17, Hungary);

Gonczol, E.; Vaczi, L. *Acta Microbiol Acad Sci Hung* 25(4): 269-275; 1978.

The transformation of Syrian hamster embryo (HEF) cells by human cytomegalovirus (HCMV) was studied. Nineteen to 24 days after inoculation of HEF with partially UV-inactivated HCMV at approx 1 plaque-forming unit/cell, rapidly multiplying foci of cells with altered morphology appeared. Only one (87-TRH-5) of 11 such foci remained capable of multiplying after isolation. This clone consisted of fibroblast-like cells with large, sometimes multiple, nuclei. Three cell lines derived from 87-TRH-5 showed a fibroepithelioid morphology with occasional multinuclear giant cells. Newborn

and weanling hamsters inoculated with 10^7 - 10^8 87-TRH-5 cells developed fibrosarcomas, as did weanling hamsters inoculated with cell lines derived from the tumors. The oncogenicity of the derivative cell lines was greater than that of the parental line. The transformed cells showed HCMV-specific cytoplasmic and surface antigen, but attempts to isolate infectious virus and to detect HCMV-specific nuclear antigens(s) failed. (14 refs)

79-2208 Size of the Intracellular Circular Epstein-Barr Virus DNA Molecules in Infectious Mononucleosis-derived Human Lymphoid Cell Lines. (Eng) Adams, A. (Dept. Medical Microbiology, Univ. Goteborg, Goteborg, Sweden); Bjursell, G.; Gussander, E.; Kolias, S.; Falk, L.; Lindahl, T. *J Virol* 29(2): 815-817; 1979.

The size of the nonintegrated circular Epstein-Barr virus (EBV) DNA molecules isolated from seven different human lymphoblastoid cell lines of infectious mononucleosis origin was determined by sedimentation analysis and by direct contour length measurements on electron micrographs. All cell lines investigated contained 10-40 EBV genome equivalents per cell, as estimated by hybridization with EBV complementary RNA. Six lines had intracellular circular EBV genomes of the same size as linear virion DNA molecules. The seventh line, established with the B95-8 strain of EBV, was the only one found to have circular EBV DNA molecules significantly smaller than virion DNA. The data show that intracellular EBV DNA circles of reduced size do not generally occur in infectious mononucleosis-derived cell lines. (12 refs)

79-2209 Establishment of a Malignant, Epstein-Barr-Virus (EBV)-negative Cell-Line from the Pleural Effusion of a Patient with Hodgkin's Disease. (Eng) Schaadt, M. (Abteilung fur Hamatologie/Onkologie, Medizinische Hochschule Hannover, D-3000 Hannover, W. Germany); Fonatsch, C.; Kirchner, H.; Diehl, V. *Blut* 38(2): 185-190; 1979.

A malignant in vitro cell line (L 428) established from the pleural effusion of a 37-yr-old woman with Hodgkin's disease (HD: nodular sclerosing type, Stage IVB) is described. The culture grew as a single cell suspension with a doubling time of 42-46 hr and a max concentration of 1.56×10^6 cells/ml. Besides large (50-80 μ m) multinuclear cells with smooth membrane surfaces or bearing a few short curled villi, medium-sized (30-50 μ m) mono- or binuclear cells with hairlike membrane protrusions and small (15-30 μ m) mononuclear cells could be identified. The cells were PAS- and acid phosphatase-positive. They showed neither B-cell nor T-cell properties; Fc receptors were present in 7% of the cells. Phagocytosis and lysozyme production could not be detected. The line did not exhibit Epstein-Barr virus-specific antigens (nuclear antigen and virus capsid antigen). According to cytogenetic studies performed immediately after the line was

established, the cells had an aneuploid karyotype with various chromosomal aberrations. The identity of eight marker chromosomes indicated that the line had a clonal origin. Intracranial heterotransplantation of cells into two nude mice resulted in tumor formation in both. Literature reports of in vitro-cultivated HD-derived cell lines are conflicting, which might be due to the fact that different cell systems (B or T lymphocytes and/or macrophages-histiocytes) might be transformed by the initiating malignant process followed by the evolution of multiple clinical features known collectively as HD. (17 refs)

79-2210 Epstein-Barr Virus RNA in Burkitt Tumor Tissue. (Eng) Dambaugh, T. (Section Infectious Disease, Dept. Medicine, Committee Virology, Kourer Viral Oncology Labs. Univ. Chicago, 910 E. 58th St., Chicago, IL, 60637); Nkrumah, F. K.; Biggar, R. J.; Kieff, E. *Cell* 16(2): 313-322; 1979.

Analysis of the viral RNA in four Burkitt's lymphoma (BL) biopsies indicated that the tumor tissue contained RNA homologous to at least 3%-6% of the DNA of Epstein-Barr virus (EBV). Most of these RNA species accumulated in the polyadenylated RNA fraction of the BL tissue. Two approaches were used to determine the location within the EBV genome of the DNA sequences that encode stable RNA in two BL biopsies, F and S, which contained 6-10 copies per cell of at least 80% of the EBV genome. With the first approach, 32 P-EBV DNA homologous to polyadenylated or nonpolyadenylated RNA's from the F, S, or R tumors was hybridized to blots of fragments of EBV DNA. With the second approach, polyadenylated or nonpolyadenylated RNA's from the F or S tumors were hybridized to separated, labeled fragments of EBV DNA in soln. The results indicated that (1) most of the viral RNA in BL tissue is encoded by approx 20% of the Hsu I D fragment, 20% of the Eco RI A/Hsu I A double-cut fragment, and 3% of the Hsu I B fragment of EBV DNA; (2) an abundant RNA species in tumor tissue is homologous to the "additional DNA" present in the W91 and Jijoye/HR-I BL isolates of EBV and absent in the B95-8 virus, an isolate of EBV from outside the Burkitt endemic region; and (3) there is little or no homology to other regions of the EBV genome. (41 refs)

79-2211 Nucleosomal Structure of Epstein-Barr Virus DNA in Transformed Cell Lines. (Eng) Shaw, J. E. (Cancer Res. Center, Dept. Microbiology and Immunology, Sch. Medicine, Univ. North Carolina, Chapel Hill, NC, 27514); Levinger, L. F.; Carter, C. W. *J Virol* 29(2): 657-665; 1979.

Micrococcal nuclease digestion was used to analyze the Epstein-Barr virus (EBV) DNA structure in nuclei of B-lymphoblastoid cell lines established from human lymphomas. Digests of virus-producing (P3HR-1), non-virus-producing

(Raji), and superinfected Raji cell nuclei were fractionated by electrophoresis on agarose gels, transferred to nitrocellulose, and hybridized to ³²P-labeled EBV DNA. The viral DNA of Raji nuclei produced a series of bands on electrophoresis whose lengths were integral multiples of a unit size that was the same as the repeat length of host DNA. Viral DNA in nuclei of P3HR-1 and superinfected Raji cells produced faintly visible bands superimposed on a smear of viral DNA that dominated the hybridization pattern. No differences were detected in the patterns when total DNA digests from Raji, P3HR-1, and an EBV DNA-negative lymphoma cell line (U-698M) were analyzed by ethidium bromide staining or by hybridization with the use of ³²P-labeled lymphoblastoid cell DNA as a probe. It is concluded that the EBV episomal DNA of Raji cells is folded into nucleosomes, whereas most of the viral DNA of P3HR-1 and superinfected Raji cells is not. This pattern of DNA organization differs significantly from that in papova viruses. (57 refs)

79-2212 [¹²⁵I] C1q-Binding Activity and Its Relationship with Anti-Epstein-Barr Virus Antibodies in Sera from Nasopharyngeal Carcinoma Patients. (Eng) Lameilin, J. P. (Unit Biological Carcinogenesis, Internatl. Agency Res. on Cancer, 150 cours Albert Thomas, 69372 Lyon Cedex 2, France); Vincent, C.; Souissi, T.; Revillard, J. P. *Eur J Cancer* 15(2): 163-171; 1979.

¹²⁵I-labeled complement component C1q-binding activity (C1q-BA) and antibody titers against Epstein-Barr (EB) viral capsid antigen (VCA), nuclear antigen (EBNA), and early antigen (EA) were determined in sera from 28 nasopharyngeal carcinoma patients (NPC) and 66 matched controls from Tunisia. C1q-BA increased with age, but did not show a significant association with stage of NPC. Significantly more sera were positive for C1q-BA among the NPC patients than among the controls. The mean titers of IgG anti-VCA and anti-EBNA antibodies and the proportion of anti-EA-positive sera were also significantly higher among the NPC patients than among the controls. The anti-VCA titers in the NPC sera increased with age for both IgG and IgA classes. IgG anti-VCA, but not IgA anti-VCA, anti-EA, or anti-EBNA, was positively correlated with the percentage of bound C1q. (34 refs)

79-2213 Superinfection of EBV-Carrying Lines with Herpes Virus Papio (HVP): Induction of Early Antigen (EA) and Inhibition of Cellular DNA Synthesis. (Eng) Steinitz, M. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Klein, G. *Eur J Cancer* 15(2): 217-222; 1979.

A possible correlation between the ability to induce early antigen and the ability to inhibit DNA synthesis was studied using an Epstein-Barr virus (EBV)-related herpesvirus [*H. papio* (HVP)] derived from the baboon virus-producer lym-

phoid cell line 9B. For comparison, the P3HR-1 variant of EBV was also studied. Both 9B and P3HR-1 viruses inhibited the DNA-stimulating effect of EBV variant B95-8 and of the B-cell mitogen *Staphylococcus aureus* on human lymphocytes, but neither inhibited DNA stimulation by the T-cell mitogen phytohemagglutinin. 9B and P3HR-1 viruses also inhibited DNA metabolism in EBV-receptor-positive cells. Pretreatment of either virus with EBV-neutralizing Burkitt's lymphoma serum abolished this inhibitory activity. The inhibiting effect was not due to residual viral genome, and the inhibition was manifested only in cells with a functionally active EBV receptor. The inability of the two viruses to immortalize normal cells and their ability to induce EA in certain cells may be related to their inhibitory effect on DNA synthesis. (24 refs)

79-2214 Physical Characterization of the Deoxyribonucleic Acids of Different Human Papilloma Viruses (HPV). (Eng) Gissmann, L. (Institut fur Virologie, Zentrum fur Hygiene, Hermann-Herder-Strasse 11, D-7800 Freiburg, W. Germany); zur Hausen, H. *Med Microbiol Immunol (Berl)* 166(1/4): 3-11; 1978.

The mol wt, buoyant density, sedimentation behavior, and cross homology of DNA from human papilloma viruses (HPV) 1, 2, and 3 were determined. HPV 1, 2, and 3 DNA appeared to be indistinguishable as far as mol wt (4.9×10^6 daltons), buoyant density (1.700 μ /ml), sedimentation values of the three circular DNA components (Co I: 22S-23S, Co II: 17S; and Co III: 16S), and homology are concerned. HPV 4 DNA, which is entirely different from HPV 1, 2, and 3 in its restriction enzyme pattern, did not hybridize with complementary RNA (cRNA) transcribed in vitro from HPV 1 DNA. The cRNA represented the entire viral genome. Therefore, the negative hybridization with HPV 4 DNA indicates that no base homology exists in any region of the two genomes. (16 refs)

79-2215 Characteristics of the Lesions and Risk of Malignant Conversion Associated with the Type of Human Papillomavirus Involved in Epidermodysplasia Verruciformis. (Eng) Orth, G. (Unite de Recherche sur l'Etiologie Virale des Cancers Humains, LA 147 CNRS, U 140 INSERM, Institut Gustave-Roussy, 94800 Villejuif, France); Jablonska, S.; Jarzabek-Chorzelska, M.; Obalek, S.; Rzeska, G.; Favre, M.; Croissant, O. *Cancer Res* 39(3): 1074-1082; 1979.

Fourteen epidermodysplasia verruciformis (EV) patients were studied to correlate the type of human papillomavirus (HPV) found in benign lesions to the clinical aspects and to the course of the disease; 9 patients were familial cases, and 6 had cancer. The type of HPV was determined by RNA-DNA filter hybridization, using complementary RNA's transcribed from the DNA's of the four types of HPV

previously identified, and by immunofluorescence studies using antisera specific for the four virus types. HPV-3 was found in seven patients presenting lesions of only the verruca plana type. These cases were mostly stationary or abortive and showed no malignant conversion. HPV-4 was detected in four patients with lesions of different types: very flat, often reddish warts; reddish plaques; and pityriasis versicolor-like pigmented or achromic plaques. All these patients showed cancers. Both types of viruses were found in two patients: HPV-3 in flat wartlike lesions and, for one patient, in large confluent pigmented plaques; and HPV-4 in reddish or pityriasis versicolor-like plaques. One of these patients had early malignant lesions (Bowen's disease) and the other had multiple carcinomas. For one patient, the type of virus could not be identified because of an insufficient amount of material. These results point to the role of virus in the pathogenesis of EV, together with genetic and immunological factors. They suggest, in addition, different oncogenic potentials for viruses involved in the disease. (29 refs)

- 79-2216 Characterization of Proteins of Human Papilloma Viruses (HPV) and Antibody Response to HPV 1.** (Eng) Pfister, H. (Institut für Virologie, Zentrum für Hygiene, Hermann-Herder-Strasse 11, D-7800 Freiburg, W. Germany); zur Hausen, H. *Med Microbiol Immunol (Berl)* 166(1/4): 13-19; 1978.

Human papilloma virus (HPV) isolates from 300 wart biopsies were characterized as HPV 1 and HPV 4 by a complement-fixation assay with specific rabbit antisera. The isolates from 30% of the biopsies were HPV 1 and 14% were HPV 4. Virus preparations from 2% did not react with either of the two antisera, and no virus could be isolated from 54% of the biopsies. An examination of the HPV 1 proteins indicated that the major structural proteins VP2 and VP3 are trypsin-sensitive. Tryptic degradation gave distinct polypeptides with mol wts of 23,000-37,000, that may be correlated to minor protein components of HPV 1 preparations. HPV 1 histonelike proteins, which comigrated with purified cellular histones upon sodium dodecyl sulfate gel electrophoresis, were analyzed in an acetic acid-urea system. The H3- and H4-like proteins differed from the cellular histones. It is not known whether this is due to modification by acetylation, as described for polyoma viruses (histone modification in these viruses appears to be correlated with oncogenicity). In a non-selected population, most children are free of HPV 1 antibodies until they are 5 yr old. Between 5 and 15 yr, about 50% of the population has HPV 1 antibody-positive serum. Serum from a patient with epidermodysplasia verruciformis, which has a tendency to malignant conversion, reacted only with HPV 4 particles when tested by immunoelectron microscopy. However, HPV 1 antibodies could be demonstrated at a titer of 1/10 by radioimmunoassay. Whether HPV 4 is causally connected with epidermodysplasia remains to be established. (11 refs)

- 79-2217 Molecular Cloning of Polyoma Virus DNA in *Escherichia coli*: Plasmid Vector System.** (Eng) Israel, M. A. (DNA Recombinant Res. Unit, Natl. Inst. Allergy and Infectious Diseases, Bethesda, MD, 20014); Chan, H. W.; Rowe, W. P.; Martin, M. A. *Science* 203(4383): 883-887; 1979.

Studies were carried out to characterize and evaluate the safety of a plasmid vector system for recombinant DNA research. In this system, *Escherichia coli* carry a recombinant plasmid that contains the entire polyoma virus genome. Insertion of the PY genome into the plasmid vector pBR322-*E. coli* χ 1776 at the restriction endonuclease *Eco*RI site leaves the entire late region of the viral genome intact, but insertion at the *Bam*HI site leaves the entire early region intact. Experiments confirmed that the entire PY genome was present in the pBR322-*E. coli* χ 1776 system. The orientation of the PY DNA insert in the recombinant plasmid molecule was ascertained by digestion with *Hind*III. Further experiments confirmed that viral-specific RNA was synthesized in bacterial minicells containing recombinant PY-pBR322 plasmids. The results of the mouse antibody production test showed that recombinant plasmids were unable to initiate productive PY infections in mice and that no free PY DNA I was present in the bacterial cells. When purified recombinant DNA preparations were first cleaved with the same restriction enzyme as was used in their construction, nearly all injected animals developed PY infection. This indicates that PY DNA, when combined with pBR322, is replicated with sufficient fidelity in *E. coli* to preserve the numerous functions required for productive infection. Even when administered to mice as massive doses of bacteria, none of the four *E. coli* χ 1776 preparations containing recombinant plasmids resulted in a PY infection after ip or sc injection, nor did they induce infection when fed repeatedly to animals for total doses of 0.4-1.0 μ g PY DNA. (25 refs)

- 79-2218 Nucleotide Sequence of the BK Virus DNA Segment Encoding Small t Antigen.** (Eng) Dhar, R. (Lab. Molecular Virology, NCI, NIH, Bethesda, MD, 20014); Seif, I.; Khoury, G. *Proc Natl Acad Sci USA* 76(2): 565-569; 1979.

The nucleotide sequence from 0.64 to 0.53 map units of the BK virus genome coding for the small tumor (t) antigen was determined. There is only one open reading frame that can code for a polypeptide of 172 amino acids, the putative small t protein. Beyond this segment, multiple termination codons are present in all three reading frames. There is considerable nucleotide and amino acid sequence homology between this region of BK virus and the analogous region of simian virus 40, especially in the proximal portion from 0.64 to 0.60 map units, which is most likely common to the small t and large T BK virus proteins. A comparison of the conserved sequences within the early papovavirus genes both confirms the evolutionary relationship between these viruses and gives an idea of the amino acid composition of the regions required

for T-antigen functions. (29 refs)

- 79-2219 Multiple 5' Terminal Cap Structures in Late Polyoma Virus RNA.** (Eng) Flavell, A. J. (Imperial Cancer Res. Fund Labs., P.O. Box 123, Lincoln's Inn Fields, London WC2A 3PX, England); Cowie, A.; Legon, S.; Kamen, R. *Cell* 16(2): 357-371; 1979.

The 5'-terminal capped structures present on late polyoma (Py) virus messenger RNA's (mRNA's) were characterized and mapped. Nuclear and cytoplasmic Py virus-specific RNA extracted from ³²P-labeled mouse embryo cells late during productive viral infection was analyzed for the presence of 5'-terminal capped structures by complete digestion with RNases T1, T2, and A, followed by two-dimensional electrophoretic fractionation. Seven major cap I structures (m⁷GpppNm¹pN²p) were observed in both cases. These termini were further characterized by digestion with penicillium nuclease P1, followed by product analysis in a variety of alternative separate systems. Each structure had an individual combination of N¹ and N² nucleotides in which N¹ was always a purine nucleotide but N² was any nucleotide subject to the single exception that m⁷GpppGmpCp is found only in low yield. Four different cap II derivatives (m⁷GpppNm¹pNm²pN³p) of four of the cap I structures were also detected in cytoplasmic RNA. None of the termini described were derived from contaminating host cell RNA. All of these cap structures mapped on the Py viral DNA genome between 66 and 71 map units, a region distant from the 5' end of the bodies of two of the three late Py mRNA's. All the Py virus-specific cap structures, however, were present in each of the purified 16S, 18S, and 19S late mRNA's. These data suggest that families of capped leader sequences of varying sizes are attached to the main body of each late Py mRNA species by a splicing mechanism. (44 refs)

- 79-2220 Amplification in the Leader Sequence of Late Polyoma Virus mRNAs.** (Eng) Legon, S. (Imperial Cancer Res. Fund Labs., P.O. Box 123, Lincoln's Inn Fields, London WC2A 3PX, England); Flavell, A. J.; Cowie, A.; Kamen, R. *Cell* 16(2): 373-388; 1979.

Ribonuclease T1 fingerprints of the three "late" polyoma virus messenger RNA's (mRNA's) showed that oligonucleotides of the leader sequence are present in multiple copies in each mRNA. These oligonucleotides, however, appeared to be unimolar in fingerprints of complete, continuous transcripts of the late strand of the viral DNA. Oligonucleotides that are represented only once in the DNA are thus reiterated in the mature mRNA's. Consequently, when mRNA was hybridized to the leader region of immobilized viral DNA, those copies present in excess of their genomic representation failed to hybridize and were released by RNase treatment. Analysis of the RNase-resistant hybrids revealed a series of leader species with complex sequence arrangements. It is suggested

that these complicated reiterated sequences are generated during the processing of a precursor RNA that extends several times around the genome. This RNA would be shortened by a series of splicing reactions that conserve sequences from the leader region and attach them to a suitable coding sequence. (35 refs)

- 79-2221 Molecular Cloning of Polyoma Virus DNA in *Escherichia coli*: Lambda Phage Vector System.** (Eng) Chan, H. W. (DNA Recombinant Res. Unit, Natl. Inst. Allergy and Infectious Diseases, Bethesda, MD, 20014); Israel, M. A.; Garon, C. F.; Rowe, W. P.; Martin, M. A. *Science* 203(4383): 887-892; 1979.

The molecular cloning of recombinants formed between the *Escherichia coli* EK2 lambda phage vector λgtWES.λB DNA and polyoma (PY) DNA and an evaluation of the infectivity of the recombinant plasmids in mouse cells in vivo and in vitro are described. The PY genome can be inserted into the lambda vector DNA in either of two orientations at the *Eco* RI site, and cleavage of the recombinant DNA preparations with *Bam*HI permitted the unambiguous mapping of the viral DNA inserts. The recombinant phages contained a monomeric or a dimeric insert. The tandem insertion of more than one copy of DNA into the λgtWES.λB vector resulted in unstable recombinants that shed extra copies of the inserts at a high frequency. Recombinant preparations containing a single copy of DNA failed to induce PY infection when inoculated parenterally in weanling mice or when tested in cultured mouse embryo cells. PY infection did occur in 2/5 mice inoculated sc with 2.8 μg of recombinant phage containing the dimeric insert (phage D) and in 2/5 inoculated with 23 μg of DNA prepared from *E. coli* infected with phage D. Injection of live *E. coli* infected with phage D failed to induce infection in any of 28 mice. Feeding of comparable infected bacteria did not induce PY infection in any of 13 mice tested. The authors conclude that in most experimental systems, tandem inserts are highly unlikely to occur. The results are highly reassuring with respect to the safety of cloning viral genomes in *E. coli*. (10 refs)

- 79-2222 Polyoma Virion and Capsid Crystal Structures.** (Eng) Adolph, K. W. (Dept. Biochemistry, Univ. Minnesota Medical Center, Minneapolis, MN, 55414); Caspar, D. L.; Hollingshead, C. J.; Lattman, E. E.; Phillips, W. C.; Murakami, W. T. *Science* 203(4385): 1117-1120; 1979.

Sodium sulfate was used to obtain large single crystals of polyoma virions and capsids suitable for x-ray structure analysis. The particles in the crystals were arranged on a body-centered cubic lattice. The small-angle x-ray reflections from the well-ordered virion crystals were weak, whereas those from the capsid crystals and from the virion crystals with comparable short-range disorder were relatively strong. The differences probably resulted, at least in part, from the

scattering contribution of the viral chromatin core. By electron microscopy (EM), the capsids appeared hollow and the virions had a solid core. Vacancies were characteristic of the crystals, especially the capsids, and they gave the sections a moth-eaten appearance. There was a close correlation between virus structure information obtained by x-ray diffraction and that obtained by EM. The bumps in the capsid surface revealed by EM were the dominant feature determining the intensity of the diffraction to a resolution of about 30 Å. The structure and variability of the viral chromatin core can then be analyzed by comparison of electron-density maps. (22 refs)

79-2223 State and Organization of Polyoma Virus DNA Sequences in Transformed Rat Cell Lines. (Eng)

Birg, F. (U. 119, Institut National de la Sante et de la Recherche Medicale, 13009 Marseille, France); Dulbecco, R.; Fried, M.; Kamen, R. *J Virol* 29(2): 633-648; 1979.

Restriction endonuclease digestion was used to analyze the polyoma (PY) DNA sequences present in tumor (T)-antigen-positive transformed rat cell lines isolated by growth in soft agar. The transformed lines were isolated as colonies growing in agar after infection of F2408 rat cells with low multiplicities of wild-type virus. Viral DNA present in the transformed cells was analyzed by fractionation of the cellular DNA on agarose gels before and after digestion with various restriction endonucleases, transfer of the DNA onto a sheet of nitrocellulose, and subsequent autoradiographic detection of the bands containing viral sequences by annealing the resulting blots to in vitro-labeled ³²P-Py DNA. Less than one copy of viral DNA per diploid equivalent of cellular DNA can be detected with this procedure. Five lines, independently derived, were studied in detail. All five lines, when examined after a minimum number of passages in culture, contained both free and apparently integrated viral DNA. The free PY DNA in three of the lines was indistinguishable, by restriction enzyme analysis, from wild-type viral DNA, whereas the two other lines also contained smaller free DNA molecules that lacked parts of the wild-type genome. The integrated DNA in the five lines existed as head-to-tail tandem repeats of unit-length Py DNA covalently attached to nonviral DNA. The same five Py-transformed rat lines were examined after further passages in culture. Free viral DNA was then either undetectable or greatly reduced in amount, whereas the high-mol-wt, integrated units persisted after passage of the cells. Ten subclones, derived from one of the five lines selected for detailed analysis, showed some variations in the quantity and size of the free viral DNA as well as minor alterations in the pattern of the apparently integrated sequences. (64 refs)

79-2224 Transformation of Human Embryonic Kidney Cells by Human Papovavirus BK. (Eng)

Purchio, A. F. (Molecular Biology Inst., Univ. California at

Los Angeles, Los Angeles, CA, 90024); Fareed, G. C. *J Virol* 29(2): 763-769; 1979.

The interaction of human papovavirus BK (BKV) with secondary human embryonic kidney (HEK) cells was investigated to define how the virus exists within its natural host. Infection of HEK cells with BKV at a multiplicity of 10 resulted in cellular lysis and degeneration within 7 days. After 30 days, multilayered colonies of transformed cells appeared; these cells were subcultured for analyses. The BK-HEK cells uniformly expressed BKV tumor (T) antigen but were only 1% V-antigen positive. They produced infectious virus and were resistant to superinfection by BKV. They reached a saturation density of 1.3×10^5 cells/cm² in medium with 5% fetal calf serum, were able to grow in medium containing 2% serum, and did not form colonies in soft agar or tumors in nude mice. Nonintegrated, superhelical BKV DNA was detected in the noncloned cells as expected, because they were persistently infected and contained RNA transcripts complementary to both early and late regions of the BKV genome. Analysis of T-antigen-positive clonal isolates of the BK-HEK cells with restriction endonucleases revealed an absence of free viral DNA and the presence of integrated BKV DNA sequences corresponding to the early region of the BKV genome. These studies demonstrate the stable transformation of human cells by BKV. However, the transformed human cells that retain and express part of the BKV genome do not fully manifest the growth properties of other papovavirus-transformed cells. (31 refs)

79-2225 Nucleotide Sequence Analysis of Two Simian Virus 40 Mutants with Deletions in the Late Region of the Genome. (Eng)

Contreras, R. (Lab. Molecular Biology, State Univ. Ghent, B-9000 Ghent, Belgium); Cole, C.; Berg, P.; Fiers, W. *J Virol* 29(2): 789-793; 1979.

Two mutants of simian virus 40, *dl*-1261 and *dl*-1262, have deletions that map between coordinates 0.90 and 0.95. Both affect the structure of the two minor virion proteins VP2 and VP3. The precise location and size of the deletions were determined by nucleotide sequence analysis. Nucleotides deleted from the two mutants were defined by digesting the mutant DNA with *AtuI* and labeling the 5' ends of the resulting fragments with [γ -³²P]ATP and T₄ polynucleotide kinase. Restriction endonuclease *HaeIII* was used for the second digestion to separate the labeled ends of the fragments. Mutant *dl*-1261 had a deletion of 54 base pairs, was temperature-sensitive for the protein defined by the D complementation group, and promoted the synthesis of shorter VP2 and VP3 polypeptides. Mutant *dl*-1262 was viable irrespective of temperature and had a deletion of 36 base pairs, 23 of which overlapped the deletion in *dl*-1261. Since these mutants produce normal VP1, the deleted regions probably have no function in the splicing of precursor RNA to the VP1 messenger RNA. (16 refs)

- 79-2226 Rapid Sequence Determination of Late Simian Virus 40 16S mRNA Leader by Using Inhibitors of Reverse Transcriptase.** (Eng) Bina-Stein, M. (Lab. Biology Viruses, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD, 20014); Thoren, M.; Salzman, N.; Thompson, J. A. *Proc Natl Acad Sci USA* 76(2): 731-735; 1979.

The problem of sequencing desired regions of selected messenger RNA's (mRNA's) was approached by using given DNA restriction fragments, which anneal to the mRNA at specific regions, as primers for the reverse transcriptase (RNA-dependent DNA polymerase) reaction. Addition of 2', 3'-dideoxynucleoside triphosphates as chain terminators during the reverse transcriptase reaction allows rapid sequence determination of the complementary DNA. This method was used to study the major late cytoplasmic 16S mRNA of simian virus 40, the message that codes for the structural coat protein VP1. The length and the nucleotide sequence of the DNA complementary to the 5' end of 16S mRNA indicated that the major leader is 200 nucleotides long and that it is joined to the body of the mRNA 44 nucleotides prior to the initiation codon. A subset of 16S mRNA's with leaders shorter than the main leader may also exist. The method described should be useful for determining spliced junctions both in coding regions in which the sequence of the genome is known but the amino acid sequence of the gene product is not known and in noncoding regions, such as untranslated leader sequences. (42 refs)

- 79-2227 Altered Pattern of Growth and Differentiation in Human Keratinocytes Infected by Simian Virus 40.** (Eng) Steinberg, M. L. (Dept. Pathology, New York Univ. Sch. Medicine, 550 First Ave., New York, NY, 10016); Defendi, V. *Proc Natl Acad Sci USA* 76(2): 801-805; 1979.

Changes in the normal patterns of growth and differentiation resulting from infection of human epidermal cells by simian virus 40 (SV40) were studied. Human epidermal keratinocytes were infected by SV40 in vitro. The structure of the developing keratinocyte colony reflected the spatial separation of cell division and keratinization in intact skin. Thymidine-incorporating cells were primarily localized at the colony periphery whereas nondividing, histologically differentiated cells accumulated in the interior. Viral infection produced a dramatic increase in the size of the proliferative population as, simultaneously, differentiation was reduced in the colony interior. These changes were manifest when SV40 tumor (T)-antigen synthesis was detectable in only a small percentage of the cells; differentiation became increasingly density-dependent as the percentage of T-antigen-positive cells rose over serial passage. The disruption of the normal pattern of growth/differentiation localization coincided with a loss of dependence on serum for growth, but preceded the appearance of other virus-induced properties associated with transformation; ie, the ability to form colonies in soft agar and independence of growth from fibroblasts. - 79-2228 Enzymatic Activities Associated with a Purified Simian Virus 40 T Antigen-related Protein.**

(Eng) Tjian, R. (Cold Spring Harbor Lab., Cold Spring Harbor, NY, 11524); Robbins, A. *Proc Natl Acad Sci USA* 76(2): 610-614; 1979.

A protein antigenically related to the simian virus 40 (SV40) A gene product was purified to near homogeneity from HeLa cells infected with the adenovirus-SV40 hybrid virus Ad2+D2 and shown to contain ATPase (ATP phosphohydrolase) and protein kinase (ATP: protein phosphotransferase) activity. Both enzymatic activities copurified with the protein through six stages, including 1 gel filtration column, 2 ion-exchange columns, and 1 heparin-affinity column. Analogous fractions from extracts of cells uninfected or infected with Ad2 alone did not contain these enzymatic activities. The D2 hybrid protein resolved into two forms (I and II) during ion-exchange chromatography. Form I, the major species (85%), eluted from diethylaminoethyl (DEAE)-Sephadex in 0.37 M NaCl and was able to catalyze the hydrolysis of ATP to ADP + inorganic phosphate at a rate of 3 micromoles/hr/mg. The remaining 10%-15% of the D2 hybrid protein consisted of form II, which eluted from DEAE-Sephadex in 0.29 M NaCl and was able to hydrolyze ATP as well as to incorporate P from ATP into either the D2 hybrid protein itself or other protein acceptors such as phosphovitin. Although both forms were able to bind DNA, the ATPase activity of form I cosedimented with SV40 DNA more efficiently than did the protein kinase activity of form II during glycerol gradient centrifugation. The ATPase activity of form I was efficiently inhibited by the addition of anti-tumor antigen (anti-T) gamma globulin to the reaction mixture, whereas control gamma globulin had no effect. Similarly, the phosphorylation of the D2 hybrid protein by form II was inhibited by anti-T gamma globulin. By contrast, phosphorylation of phosphovitin was specifically inhibited by antibody only when the immune complex was removed from the reaction mixture. Thus, it appears likely that one and possibly two enzymatic activities are carried out by the D2 hybrid protein. (26 refs)

- 79-2229 Phosphorylation of T-Antigen and Control of T-Antigen Expression in Cells Transformed by**

Wild-Type and *tsA* Mutants of Simian Virus 40. (Eng) Edwards, C. A. (Lab. Molecular Biology, Natl. Inst. Arthritis, Metabolism and Digestive Diseases, Bethesda, MD, 20014); Khoury, G.; Martin, R. G. *J Virol* 29(2): 753-762; 1979.

Chinese hamster lung (CHL) cells transformed by wild-type simian virus 40 (SV40; cell line CHLWT15) or transformed by the SV40 mutants *tsA30* (cell lines CHLA30L1 and CHLA30L2) or *tsA239* (cell line CHLA239L1) were used to determine the rates of turnover and synthesis of the tumor (T)-antigen protein and the rate of turnover of the phosphate group(s) attached to the T antigen at both the permissive and restrictive temperatures. The phosphate group turned over several times within the lifetime of the protein to which it was

attached, with the exception of the phosphate group in the *tsA* transformants at 40 C, which turned over at the same rate as the T-antigen protein. The steady-state levels of the T antigens [mol wts 92,000 (92K) and 17K] and the amount of SV40-specific RNA were also determined in each of the lines. The CHLA30L1 line contained two to three times more early SV40 RNA than the CHLA30L2 line. Although neither line formed colonies in agar at 40 C, CHLA30L1 overgrew a normal monolayer at 40 C. The rate of 92K T-antigen synthesis was 1.5 times faster in CHLA30L1 than in CHLA30L2 at 33 C and 4 times faster at 40 C. The different phenotypes of these two presumably isogenic cell lines seemed to be related to the levels of the T antigens. The ratios of the 92K T antigen to the 17K T-antigen were similar in the two lines. Transformed CHL cell lines, unlike transformed mouse 3T3 cell lines, were found to contain very small amounts of the 56K T antigen. (26 refs)

- 79-2230 Intracellular Forms of Simian Virus 40 Nucleoprotein Complexes. I. Methods of Isolation and Characterization in CV-1 Cells.** (Eng) Fernandez-Munoz, R. (Virologia Centro "Ramon y Cajal", Madrid-34, Spain); Coca-Prados, M.; Hsu, M. T. *J Virol* 29(2): 612-623; 1979.

A new method for isolating intracellular forms of simian virus 40 (SV40) nucleoprotein (NP) complexes from SV40-infected CV-1 cells late in the infectious cycle is described, along with the initial characterization of their physical and biochemical properties. In contrast to the Triton extraction method, which yields only a 60S-70S complex, this new procedure yielded three SV40 NP complexes: complex I, complex II, and the mature virion (V). The three NP complexes differed in physical as well as biochemical properties. Complex I, which is only a small portion of the total SV40 NP complexes late during infection, was active in synthesizing both SV40-specific DNA and RNA. On the basis of its properties, it is suggested that complex I is the active chromatin of SV40. Pulse-labeling experiments suggested the following metabolic pathway: I is converted to II, which in turn is converted to V. Conversion of complex I to II occurred shortly after the completion of SV40 DNA replication and resulted in inactivation of the biosynthetic activities of I. The role of complex II in the SV40 infection cycle is not known. (21 refs)

- 79-2231 Evidence that the RNA Polymerase Usually Does Not Make a Complete Transcript of the Late Strand of Simian Virus 40 DNA.** (Eng) Fried, A. H. (33 Kings Circle, Malvern, PA, 19355). *J Virol* 29(2): 466-474; 1979.

A model for the transcription of the late (L) strand of simian virus 40 DNA, in which late after the infection of permissive monkey cells, RNA polymerase makes a complete transcript of the L DNA strand before terminating transcription, was

evaluated. If the model is correct, the rate of synthesis of all RNA sequences from the L DNA strand should be equal. About one-half of the L DNA strand is transcribed into late messenger RNA (mRNA) sequences and the other half into late degraded RNA (dRNA) sequences, which do not leave the nucleus. Using glucosamine to reduce the size of the intracellular uridine triphosphate pool before and after pulse-labeling CV-1 monkey cells with radioactive uridine, a pulse-chase experiment was performed to determine the half-lives of these sequences. The half-life of the late dRNA sequences was determined to be 4 min. On the av, the late mRNA sequences were degraded more slowly. In a parallel experiment with similarly treated cells, it was shown that after a 2-min label with radioactive uridine, there was only 0.2 times as much radioactivity in the late dRNA sequences as in the late mRNA sequences in the total cellular RNA population. When the results were combined, the rate of synthesis of the late dRNA sequences was calculated to be at most 0.3 times that of the late mRNA sequences. Consequently, the results provide strong evidence that when RNA polymerase transcribes the late mRNA sequences, it usually terminates transcription before all the late dRNA sequences are transcribed. (23 refs)

- 79-2232 Karyology and Tumorigenicity of a Simian Virus 40-Transformed Chinese Hamster Cell Clone.** (Eng) Lehman, J. M. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO, 80262); Trevor, K. *J Cell Physiol* 98(3): 443-450; 1979.

To determine whether specific chromosomal changes are associated with tumorigenicity, a pseudodiploid clone of Chinese hamster cells transformed in vitro with simian virus 40 (SV40) was injected into nude mice through three successive passages. The cells were cultivated briefly in vitro between each animal inoculation. Palpable nodules of poorly differentiated fibrosarcomas appeared within 10-14 days following injection. The morphology of all tumor cell populations resembled that of the original Wt-2 clone, all in vitro populations cloned from the tumors were 93%-99% SV40 tumor (T)-antigen positive and SV40 V-antigen negative, and all cell populations demonstrated definite modes in the pseudodiploid range. Frequently noted abnormalities included the addition of chromosomes 1 and 2, recurrence of marker chromosomes that were morphologically unidentifiable, loss of one of the two X chromosomes, and loss of autosomes 5, 6, and 11. The X-chromosome deletions occurred with the same frequency in all cell lines, whereas the addition of chromosomes 1 and 2 tended to occur more often in the tumor cell lines than in Wt-2. The appearance of marker chromosomes and the loss of autosomes 5, 6, and 11 were correlated with tumorigenicity. However, there was no association of tumorigenicity with a specific addition or loss of a particular chromosome(s). (17 refs)

79-2233 Expression of SV40-related T-Antigen in Cell Cultures of Human Meningiomas. (Eng) Zang, K. D. (Institut für Humangenetik, Universität des Saarlandes, D-6650 Hamburg/Saar, W. Germany); May, G.; Fischer, H. *Naturwissenschaften* 66(1): 59; 1979.

A positive reaction to at least one of three hamster antisera to simian virus 40 (SV40) T antigen was obtained in 11/27 cell cultures of human meningiomas. When tested by indirect immunofluorescence for the presence of SV40 antibodies, sera from all T-positive meningioma patients reacted positively on SV40-infected CV1 cells. Although 13/23 tested cultures had abnormal karyotypes, no correlation was detected between karyotype and T-antigen reactivity. (7 refs)

79-2234 A Stretch of "Late" SV40 Viral DNA about 400 bp Long Which Includes the Origin of Replication Is Specifically Exposed in SV40 Minichromosomes. (Eng) Varshavsky, A. J. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139); Sundin, O.; Bohn, M. *Cell* 16(2): 453-466; 1979.

DNA fragments produced from formaldehyde-fixed (F-F) or unfixed simian virus 40 (SV40) minichromosomes (mCS's) by multiple-cut restriction endonucleases were examined. Digestion of unfixed mCS's with Hae III generated all 10 major limit-digest DNA fragments as well as partial cleavage products. In contrast, Hae III digestion of the F-F mCS's produced only the F limit-digest fragment, which is located in the immediate vicinity of the origin of replication, spanning nucleotides 5169 and 250 on a previously described DNA sequence map. This 300-base pair (bp) fragment was released as naked DNA from F-F, Hae III-digested mCS's following pronase-sodium dodecyl sulfate (SDS) treatment or SDS treatment alone. In the latter case, the remainder of the mCS retained its compact configuration. Thus, the F fragment in mCS's is not only accessible to Hae III at its ends, but is also neither formaldehyde cross-linked into any SDS-resistant nucleoprotein structure nor topologically "locked" within the compact mCS particle. This same fragment was preferentially produced during the early stages of digestion of unfixed mCS's with Hae III, and its final yield in the exhaustive digest was significantly higher than that of other limit-digest fragments. Similar results were obtained upon digestion of unfixed or F-F mCS's with Alu I. Of approx 20 major limit-digest DNA fragments, only 2 (F and P, encompassing nucleotides 5146 to 190 and 190 to 325, respectively) were produced by Alu I from the F-F mCS's. Mbo I, Mbo II, Hind III, Hin II + III, and Hinf I did not produce any significant amount of limit-digest DNA fragments from F-F mCS's. It is suggested that a specific region of the "late" SV40 DNA approx 400 bp long is uniquely exposed in the compact mCS. This region is the origin of replication, and it contains binding sites for tumor antigen, specific tandem repeated sequences, and, apparently, the promoters for synthesis of late SV40 messenger RNA's. (34 refs)

79-2235 Effect of Alkylation on the Physical Properties of Simian Virus 40 T-Antigen Species. (Eng) Crawford, L. V. (Dept. Molecular Virology, Imperial Cancer Res. Fund, London WC2A 3PX, England); O'Farrell, P. Z. *J Virol* 29(2): 587-596; 1979.

Large and small species of simian virus 40 (SV40) tumor (T) antigen were analyzed by immunoprecipitation and two-dimensional gel electrophoresis, either directly or after reduction and alkylation of the antigens with N-ethylmaleimide. Alkylation improved the resolution of large-T antigen by two-dimensional gel electrophoresis and was necessary for the resolution of small-t antigen. Large T formed a streak from pH 6.5 to 6.9 on isoelectric focusing gels. Small t formed a sharp protein spot at pH 7.2 when subjected to electrophoresis under nonequilibrium conditions. Alkylation decreased the electrophoretic mobility of both T-antigen species. The apparent increase in mol wt may be due to the association of N-ethylmaleimide with the cysteine-rich regions of these proteins. Viable deletion mutants of SV40 that do not induce the synthesis of small t but produce small-t-related polypeptides were used to localize the cysteine-rich region of small-t to between 0.54 and 0.59 units on the genetic map of SV40. (42 refs)

79-2236 Persistence and Recombination of Minicircular SV 40 DNA in Permissive Cells. (Eng) Chowdhury, K. (Institut für Virusforschung, Deutsches Krebsforschungszentrum, Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Ruben-Barretto, M.; Sauer, G. *Z Krebsforsch* 93(1): 31-44; 1979.

Deleted microcircular simian virus 40 (SV40) DNA preparations containing 10%-25% deletions were used to transfect permissive CV-1 monkey cells to study whether SV40 DNA can persist in a plasmid-like state. Addition of wild-type DNA to the deleted microcircular DNA prior to transfection permitted the replication of all deleted molecules, but in the absence of complementary helper DNA, only the least-deleted molecules (10%-15% deletion) were able to replicate. When microcircular DNA containing relatively large deletions (15%-25% deletion) was employed for transfection, no viral DNA replication or infectious virus production was detected for up to 4 wk postinfection. Between 5 and 8 wk after infection, however, a cytopathic effect developed, and virus-specific antigens were expressed, replication of SV40 DNA occurred, and viral progeny appeared. The data showed that viral DNA molecules containing deletions that had persisted in the cell for 4 wk in an unexpressed state subsequently recombined to form DNA molecules that gave rise to infectious virions. In no case did a transfected carrier culture contain replicating SV40 DNA in the absence of virion production. (27 refs)

- 79-2237 Nucleotide Sequence at the 5' Terminus of Adenovirus 2 Late Messenger RNA.** (Eng) Lockard, R. E. (Dept. Biology and Center Cancer Res., Massachusetts Inst. Technology, Cambridge, MA, 02139); Berget, S. M.; RajBhandary, U. L.; Sharp, P. A. *J Biol Chem* 254(3): 587-590; 1979.

The nucleotide sequence of the 5'-terminal undecanucleotide common to all the late viral messenger RNA's (mRNA's) synthesized from the region of the adenovirus type 2 (Ad2) genome mapping between 16.0 and 92.0 units was studied. Two-dimensional fingerprint analysis of 5'-³²P-labeled RNA followed by two-dimensional thin-layer chromatography revealed a single oligonucleotide that appeared to be derived from the capped 5' termini of the late Ad2 mRNA's. As determined by a two-dimensional homochromatographic analysis of a partial nuclease P1 digest, the nucleotide sequence of this oligonucleotide was (³²P)m⁶AmCUCUCU-UCCGp. The 5'-terminal undecanucleotide sequence from late Ad2 mRNA was compared with the 5'-terminal nucleotide sequences of human, rabbit, and mouse α - and β -globin mRNA's. Each of these mRNA's contained the sequence ³'CUUPyPyG', which is complementary to the sequence ¹'GAAGGC' present close to the 3' terminus of the 18S ribosomal RNA of most eukaryotes. It should now be possible to locate the major late promoter within the adenoviral genomic DNA sequence. (42 refs)

- 79-2238 Normal Human Tissues Contain RNA and Antigens Related to Infectious Adenovirus Type 2.** (Eng) Jones, K. W. (Inst. Animal Genetics, Univ. Edinburgh, Kings Bldgs., West Mains Road, Edinburgh, UK); Kinross, J.; Maitland, N.; Norval, M. *Nature* 277(5694): 274-279; 1979.

To identify possible human RNA sequences related to adenovirus type 2 (Ad2) viral DNA in uninfected human organs, placenta RNA was hybridized to Ad2 DNA, human DNA, or λ phage DNA. The placenta RNA hybridized to a great degree with the human DNA, to a moderate degree with Ad2 DNA, and not at all with the phage DNA. Hybridization of placenta RNA with restriction endonuclease-digested Ad2 DNA showed four regions of hybridization: the first began (rightward limit) at 7.5 units on the Ad2 map, the second began (leftward limit) at approx 26 units, the third extended from approx 37-58.5 units, and the fourth was between approx 70.7 and 75.9 map units. The first region contains the transforming gene(s) of Ad2. The same pattern was found using RNA from adult human liver and RNA from the liver, kidney, brain, and spleen of a gorilla. RNA's from human cell lines in permanent culture and from chickens showed little or no hybridization. The human placenta RNA-Ad2 DNA hybrids were reasonably thermally stable. Immunologic experiments showed that rabbit cells infected with Ad2 contained certain antigens that were not present in uninfected rabbit or human cells in culture. Some of these antigens were identical to tissue antigens present in most human placenta samples and in gorilla tissues. (32 refs)

- 79-2239 Parental Adenovirus Type 2 Genomes Recovered Early or Late in Infection Possess Terminal Proteins.** (Eng) Straus, S. E. (Dept. Pathology, Washington Univ. Sch. Medicine, St. Louis, MO, 63110); Sergeant, A.; Tigges, M. A.; Raskas, H. J. *J Virol* 29(2): 828-832; 1979.

An attempt was made to determine whether the intranuclear parental DNA of adenovirus 2 is associated with terminal proteins using convenient assay. Restriction fragments bearing terminal proteins aggregate and do not enter agarose gels. Proteolytic digestion of the aggregated complexes liberates equimolar amounts of each terminal fragment, which then migrates normally in the gel matrix. At both early (3 hr) and late (18 hr) times after infection of KB cells with adenovirus 2, > 90% of the parental nuclear viral genomes were found to exist as complexes that contain terminally linked proteins. Density shift experiments employing 5-bromo-2'-deoxyuridine indicated that these parental DNA molecules remain complexed with terminal proteins after DNA replication. The persistent linkage of proteins to the termini of intranuclear viral DNA suggests that these proteins have an essential role in adenovirus replication. (15 refs)

- 79-2240 Regulation of the Appearance of Cytoplasmic RNAs from Region 1 of the Adenovirus 2 Genome.** (Eng) Spector, D. J. (Dept. Pathology, Div. Biology and Biomedical Sciences, Washington Univ. Sch. Medicine, St. Louis, MO, 63110); McGrogan, M.; Raskas, H. J. *J Mol Biol* 126(3): 395-414; 1978.

The time course of appearance of cytoplasmic RNA's coded by the region 0-10.7 on the adenovirus 2 (Ad2) genome (early region 1) was examined using specific DNA probes. Hybridization with restriction endonuclease fragments of viral DNA resolved five cytoplasmic RNA's (22S, two 13S, two 9S RNA's). The 22S RNA contained sequences to the right of map position 4.4. 13S-L RNA mapped to the left of position 4.4, and 13S-f RNA was transcribed from two separate regions to the right of 4.4. Each 13S RNA shared 3' sequences with a distinct 9S RNA. 9S-L RNA mapped to the left of 4.4, and 9S-polypeptide IX (9S-IX) hybridized only to the 8.7-10.7 fragment [8.7-10.7 RNA is the messenger RNA (mRNA) for polypeptide IX]. Sequences in 13S-f RNA were also present in the 22S species. During productive infection, each RNA species had a characteristic rate of appearance in the cytoplasm. 22S and 13S-L RNA accumulated at a constant rate throughout infection. Initially, 13S-f RNA appeared at a substantially lower rate than 22S and 13S-L RNA's. At late times, accumulation of 13S-f RNA was stimulated > 50-fold, until its appearance exceeded that of the other early RNA's. The 9S RNA's were detected only after viral DNA replication had begun. The rate of appearance of each approached that of its colinear 13S RNA. The results show that there is a complex regulatory pattern for region 1 RNA's. (48 refs)

- 79-2241 Adenovirus Aggregation and Preservation in Extracellular Environment.** (Eng) Galdiero, F. (Cattedra Facolta di Medicina e Chirurgia 1, Universita di Napoli, Istituto di Microbiologia, S. Andrea della Dame 2, 80138 Naples, Italy). *Arch Virol* 59(1/2): 99-105; 1979.

Sucrose gradient velocity sedimentation studies demonstrated that adenovirus type 2 aggregation depends on: ionic strength, which must be between 0.005 and 0.05 M NaCl; pH, with 90% aggregation occurring at pH 4-5; particle concentration, which was optimum at 5×10^{11} particles/ml; and temperature (25-37 C). Below 20 C, aggregation decreases, and below 4 C no aggregation occurs. (15 refs)

- 79-2242 Structure of the Components of the Adenovirus-Simian Virus 40 Hybrid Population Ad2++HEY And Reciprocal Molecular Interactions.** (Eng) Van Roy, F. (Lab. Molecular Biology, State Univ. Ghent, Ledeganckstraat 35, 9000 Ghent, Belgium); Fiers, W. *J Mol Biol* 126(4): 691-720; 1978.

The different components of the adenovirus type 2 (Ad2)-simian virus 40 (SV40) hybrid population Ad2++HEY were purified, and their structures and reciprocal interactions in African green monkey kidney cells were studied. Two of the three defective hybrid virions in Ad2++HEY, HEY-1.4 and HEY-2.4, contained more than one complete SV40 genome length, with the excess SV40 DNA being arranged in head-to-tail tandem repetition. In the presence of helper Ad2 virions, the HEY-1.4 and HEY-2.4 particles interconverted readily in the monkey cells, and they were present in their original relative amounts (HEY-1.4 particles were most numerous). With helper Ad5 virions, however, HEY-2.4 particles predominated. Although HEY-1.4 particles were normally more abundant in the population, they showed less ability to yield nonhybrid SV40 progeny than the HEY-2.4 particles. Excision of SV40 DNA from the HEY-1.4 genome was found to be an accurate process, and there was no evidence of the acquisition of Ad-specific or host cellular DNA sequences. Although the genome of the excised nonhybrid SV40 progeny differed slightly from that of SV40 strain 776, there was no reason to believe that these changes were causally related to the integration and excision phenomena. (62 refs)

- 79-2243 Simian Virus 40 Specific Proteins on Surface of HeLa Cells Infected with Adenovirus 2-SV40 Hybrid Virus Ad2+ND2.** (Eng) Deppert, W. (Max Planck Inst. Biophysical Chemistry, PO Box 968, D-3400 Gottingen, W. Germany); Pates, R. *Nature* 277(5694): 322-324; 1979.

Immunofluorescence microscopy using a rabbit anti-T serum prepared against purified denatured tumor (T)-antigen was used to visualize simian virus 40 (SV40)-specific proteins on the cell surface of HeLa cells infected with the nondefective

adenovirus 2-SV40 hybrid virus Ad2+ND2. The rabbit anti-T serum specifically precipitated the SV40-specific 56,000-dalton (56K) and 42K proteins. Staining with this serum revealed perinuclear or cytoplasmic U-antigen fluorescence in about 80% of the Ad2+ND2-infected cells. Ad2-infected HeLa cells treated with the rabbit anti-T serum did not exhibit any fluorescence staining. The nuclei of cells fixed with methanol-acetone, but not those of cells fixed with formalin, were stained by the serum. Formalin-fixed Ad2+ND2-infected HeLa cells stained with rabbit anti-T serum showed cell-surface fluorescence, indicating that the surface fluorescence was associated with the Ad2+ND2-infected cells. No cell-surface fluorescence was obtained when Ad2+ND2-infected cells were stained after extensive absorption of the serum on methanol-fixed SV101 cells, a procedure that reduced T- and U-antibody titers by 80%. The data provide evidence that at least part of the SV40-specific 56K and 42K proteins located in the plasma membranes of Ad2+ND2-infected cells are located on the cell surface. This location is compatible with the hypothesis that these proteins carry the antigenic determinants for SV40 tumor-specific transplantation antigen. (18 refs)

- 79-2244 Simian Virus 40 T- and U-Antigens: Immunological Characterization and Localization in Different Nuclear Subfractions of Simian Virus 40-transformed Cells.** (Eng) Deppert, W. (Max Planck Inst. Biophysical Chemistry, D-3400 Goettingen, W. Germany). *J Virol* 29(2): 576-586; 1979.

Simian virus 40 (SV40)-transformed 3T3 cells (clone SV101) and HeLa cells infected by the nondefective adenovirus 2 (Ad2)-SV40 hybrid viruses Ad2+ND1 and Ad2+ND2 were analyzed for SV40 tumor (T) and U antigens, respectively, using Syrian golden hamster SV40 tumor sera before and after they were absorbed to remove U antibodies. The results showed that T- and U antigens could be defined by separate classes of antigenic determinants and that the U antigen determinants in SV40-transformed cells and in hybrid virus-infected cells were similar. The apparent discrepancy in the subcellular location of U antigen in SV40-transformed cells (nuclear location) and in hybrid virus-infected cells (perinuclear location), as determined by immunofluorescence staining of methanol/acetone-fixed cells, could be resolved by treating hybrid virus-infected cells with a hypotonic KCl soln before fixation. After this treatment, hybrid virus-infected cells also showed nuclear U antigen staining. The possibility of an association of T and U antigens with different nuclear subfractions in SV40-transformed cells was investigated. SV40-transformed cells were lysed with hypotonic buffer containing Nonidet P-40, and the nuclei were further divided into a nuclear matrix fraction and a high-salt nuclear extract. Analysis of the nuclear matrices by immunofluorescence microscopy with T+U+ and T+U- hamster SV40 tumor serum revealed that U antigen remained associated with the nuclear matrices, whereas T antigen could not be detected in this nuclear subfraction. However, T antigen could be im-

munoprecipitated from the nuclear extracts of the SV40-transformed cells. (38 refs)

- 79-2245 Transformation of Rat Cells by the Hybrid Virus Ad2⁺ HEY.** (Eng) Galloway, D. A. (Cold Spring Harbor Lab., Cold Spring Harbor, NY, 11524); Lukanidin, E.; Topp, W. C.; Sambrook, J. *J Gen Virol* 42(2): 339-356; 1979.

Four Fischer rat embryo cell lines transformed with DNA from a hybrid simian virus 40 (SV40)-adenovirus 2 (Ad2) virus, adenovirus 2 HEY (Ad2⁺ HEY), were studied with respect to phenotypic characteristics, synthesis of virus antigens, rescue of SV40 genomes, content of virus DNA, and the arrangement of integrated virus DNA sequences. All four transformed cell lines synthesized SV40 tumor (T) antigen, but only one expressed Ad2 T antigen. None of the transformed cell lines expressed late antigens; eg, SV40 V antigen or Ad2 fiber antigen. This pattern of virus antigen expression suggests that the cell lines were transformed by the SV40 moiety of the hybrid virus. SV40 could be rescued from 3/4 cell lines by fusion with permissive cells. No Ad2 DNA sequences were detected in the rescued genomes. Three cell lines contained 0.5-2 copies of SV40 and Ad2 DNA sequences per diploid quantity of rat cell DNA. The fourth line contained 5 copies of SV40 DNA and 20 copies of the Ad2 genome. At least three of the cell lines contained DNA sequences from the helper Ad2 in addition to sequences from the Ad2⁺ HEY genome. The location of the virus DNA sequences among the products of digestion of transformed rat cell DNA by restriction endonucleases was determined by hybridization. The pattern that emerged was very complex, suggesting multiple insertions of both adenovirus and SV40 DNA sequences. The findings indicate that Ad2⁺ HEY sequences are integrated into the DNA of the transformed cell lines and cause these cells to express virus antigens and have the phenotype of transformed cells. (43 refs)

- 79-2246 Immunoprecipitation of Protein Kinase Activity from Adenovirus 5-infected Cells Using Antiserum Directed Against Tumour Antigens.** (Eng) Lassam, N. J. (Dept. Biology, McMaster Univ., Hamilton, Ontario, Canada L8S 4K1); Bayley, S. T.; Graham, F. L.; Branton, P. E. *Nature* 277(5693): 241-243; 1979.

Studies were conducted to determine if the transforming gene products of human adenovirus type 5 (Ad5) possess protein kinase activity. Antiserum against viral transformation proteins was obtained from hamsters bearing tumors induced by Ad5-transformed hamster cells. Cytoplasmic extracts were prepared from Ad5-infected and mock-infected human KB cells and immunoprecipitated with immune or control nonimmune serum. Washed immune complexes were then incubated in the presence of [γ -³²P]ATP, and the samples were analyzed by sodium dodecyl sulfate-polyacrylamide gel

electrophoresis. The results indicate that an Ad5 transformation-specific protein is either a protein kinase or is associated with one. Whether this activity is due to a virus-coded or virus-induced cellular enzyme is not clear. With transformation-defective host range mutants of Ad5, enzyme activity was reduced, suggesting that these mutants are at least partly deficient in this function. These results are similar to those obtained with Rous sarcoma virus and indicate that protein kinase activity is associated with the transforming proteins of both an RNA and a DNA tumor virus. Therefore, alterations in protein phosphorylation may be a general mechanism by which all tumor viruses induce cellular transformation. (14 refs)

- 79-2247 Autoregulation of Adenovirus Type 5 Early Gene Expression. III. Transcription Studies in Isolated Nuclei.** (Eng) Blanton, R. A. (Dept. Microbiology, Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA, 17033); Carter, T. H. *J Virol* 29(2): 458-465; 1979.

To analyze the mechanism behind the overproduction of early virus RNA by an early temperature-sensitive mutant (*ts* 125) of adenovirus type 5 (Ad5) at the restrictive temperature, the rate of adenovirus RNA synthesis was compared in nuclei isolated from cells infected with Ad5 or *ts*125. The cells were infected at 40.5 C in the presence of the DNA synthesis inhibitor 1- β -D-arabinofuranosylcytosine. In nuclei isolated at various times postinfection (PI), the maximum amount of virus RNA synthesis occurred at 6 hr PI, after which time virus RNA synthesis declined in nuclei from wild-type infections but remained high in nuclei from *ts*125 infections. At 12 hr PI, the amount of virus RNA synthesis was 8- to 11-fold higher in nuclei from *ts*125 infections than in nuclei from wild-type infections. However, the kinetics of virus RNA synthesis in nuclei isolated from both infections were similar. When a *ts*125-infected culture was shifted to 32 C for 3 hr (12-15 hr PI) before nucleus isolation, the amount of virus RNA synthesis in the isolated nuclei was reduced to nearly wild-type levels. A pulse-chase experiment showed little difference in degradation rates of virus RNA in isolated nuclei from wild-type and *ts*125 infections. Hybridization of RNA synthesized in vitro to restriction fragments of Ad5 DNA was consistent with early virus RNA. These results support the idea that the 72,000-dalton DNA-binding protein encoded by the mutant gene in *ts*125 can regulate early adenovirus gene expression by inhibiting initiation of transcription of the adenovirus genome. (30 refs)

- 79-2248 Virus-associated RNA Synthesis in Adenovirus Type 12 Infections (Meeting Abstract).** (Eng) Geis, A. (Dept. Pathology, CMDNJ-Rutgers Medical Sch., Piscataway, NJ, 08854); Fohring, B.; Raska, K. *Fed Proc* 38(3, part 2): 1071; 1979. (no refs)

79-2249 Activation of an Endogenous Oncogenic Virus by Human Adenovirus in Mice. (Eng) Ohmori, M. (Dept. Pathology, Okayama Univ. Medical Sch., Okayama 700, Japan); Ohtsuki, Y.; Kobayashi, S. *Z Krebsforsch* 93(1): 45-56; 1979.

The oncogenicity of viral particles prepared from adenovirus type 12 (Ad12)-induced tumors in C3H/BiF mice was studied. The intracisternal and intercellular virus particles found in the Ad12-induced tumors resembled A- and C-type particles. Within 24 mo after they were inoculated with a cell-free extract from these tumors, 12/40 mice developed malignant lymphomas. Analysis of four of these lymphomas revealed lymphocytic leukemia in three cases and myeloid leukemia in one. The induced lymphomas contained occasional virus particles resembling intracisternal A particles and immature C-type particles. Only a few intracisternal A particles and C-type particles were found in two spontaneous hepatomas and in 4-nitroquinoline 1-oxide-induced tumors in C3H/BiF mice. Furthermore, only the original Ad12-induced tumor cells were shown to contain tumor-specific antigen by fluorescence microscopy. The fluorescent antigens were associated with the intracisternal A particles but not the C-type particles. The induced lymphomas and the spontaneous hepatomas did not contain tumor-specific antigen. The endogenous intracisternal A- and/or C-type virogenes might be activated by Ad12, causing their appearance in the tumor cells. These viruses may be responsible for the induction of malignant lymphoma. (37 refs)

79-2250 A Model for Assembly of Type-C Oncornaviruses. (Eng) Bolognesi, D. P. (Dept. Surgery, Duke Univ. Medical Center, Durham, NC, 27710); Montelaro, R. C.; Sullivan, S. J.; Frank, H.; Schafer, W. *Med Microbiol Immunol (Berl)* 164(1/3): 97-113; 1977.

The morphology and structural components of C-type oncornaviruses are discussed in relation to a proposed model for the assembly of these viruses. According to this model: (a) complexes of virus envelope components migrate to the cell surface and are inserted in the membrane at the site of virus budding; (2) uncleaved precursor molecules to the internal virus polypeptides are transported to the budding site; (3) proteolytic enzymes cleave the precursor molecules at the appropriate sites, generating individual structural elements of the virus; and (4) the virion components associate with themselves and/or other molecules to form the substructures found in the mature virus. (62 refs)

79-2251 Role of RNA Polymerase II in Type C Virus Induction (Meeting Abstract). (Eng) Snead, R. M. (Frederick Cancer Res. Center, Frederick, MD, 21501); Ramsburg, M. E.; Long, C. W. *Fed Proc* 38(3, part 1): 812; 1979. (no refs)

79-2252 Type C Virus Induced by Iododeoxyuridine in the Human Embryonic Cell Strain HEL-12. (Eng) Prochownik, E. V. (Dept. Pathology, Div. Biological Sciences, Univ. Chicago, Chicago, IL, 60637); Panem, S.; Kirsten, W. H. *J Gen Virol* 42(2): 399-403; 1979.

The induction of a C-type virus from a strain of human embryonic lung cells (HEL-12) by iododeoxyuridine (IUdR) was examined at various times during in vitro propagation. IUdR did not elicit C-type virus production immediately following initiation of cultures from frozen primary HEL-12 cells. After overnight treatment with 30 µg/ml IUdR, the cells expressed viral antigens and produced a C-type virus between the 25th and 80th day of in vitro growth. Production of the induced C-type virus was transient. Single-cell clones of the parental HEL-12 strain were likewise susceptible to C-type virus production by IUdR. During the interval of spontaneous C-type virus production and max antigen expression, which occurred between 80 and 120 days of in vitro growth, virus yield was not enhanced by the addition of an otherwise virogenic dose of IUdR to the growth medium of uncloned HEL-12 cells. (13 refs)

79-2253 In-Vivo Expression of a C-Type RNA Virus in Rat Ventral Prostate Epithelial Cells. (Eng) Anderson, K. M. (Oncology Lab., Dept. Medicine, Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL, 60612); Rubenstein, M.; Seed, T. M. *Biochem Biophys Res Commun* 86(2): 402-406; 1979.

During evaluation of a procedure for separating rat ventral prostate epithelial cells from connective tissue cells, isolated fractions were examined by transmission electron microscopy. Characteristic C-type RNA viruses were seen budding from or in close proximity to the plasma membranes of isolated epithelial cells. Most of the particles were associated with fraction 4 at the gradient cushion interface, which is enriched in epithelial cells. Similar particles were much less evident in fractions containing fewer epithelial cells (fractions 1-3) and in intact prostatic tissue. The particles were not associated with cells of connective or vascular tissue origin. To date, 3/5 individually processed rat prostates were positive for the virus: 2/3 glands were from Sprague-Dawley rats, and one was from a Long-Evans rat. The prostate from a Wistar rat appeared negative. Dissociation of the prostatic tissue and sedimentation of the cells through a Ficoll gradient facilitated detection of the virus. (14 refs)

79-2254 Characterization of a Retrovirus Isolated from Normal Mink Cells Co-cultivated with a Dog Mammary Tumour. (Eng) Ahmed, M. (John Smith Memorial Cancer Res., Pfizer Inc., Maywood, NJ, 07607); Yeh, J.; Stephens, R.; Holden, H. E.; Schlom, J.; Drohan, W.; Howard, D. K. *J Gen Virol* 42(1): 179-184; 1979.

A retrovirus antigenically distinct from known B-, C-, and D-type viruses was isolated from normal mink (*Mustela vison*) lung cells that had been cocultivated with 5-iododeoxyuridine- and dexamethasone-treated dog mammary tumor cells. Cytogenetic studies of the virus-releasing coculture showed mitotic figures identical to the normal mink cell line (Mv1Lu) except for a low frequency of cells with extensive chromosomal breakage and uncoiling. The new virus had a buoyant density of 1.16 g/ml and contained 60S RNA and a reverse transcriptase that preferred Mn^{2+} over Mg^{2+} for DNA synthesis. This enzyme utilized poly(rA).oligo(dT) more efficiently than poly(dA).oligo(dT), and it could synthesize DNA copies from endogenous RNA. Morphologically, it was a typical C-type virus. The virus readily infected mink, dog, and other mammalian cells. Hybridization studies showed that normal mink DNA contains multiple copies of proviral sequences of this newly isolated virus. Serological analyses indicated that the mink endogenous virus contains in its core protein, in addition to the interspecies C-type determinant, an antigenic component related to one of the determinants found in feline leukemia virus p30 protein. This determinant is not present in the Rauscher leukemia virus, RD114 virus, or simian sarcoma virus. Mink cells maintained for > 2 yr showed no spontaneous release of a retrovirus. This suggests that coculturing of mink cells with other cell lines may provide the necessary information for active multiplication of endogenous C-type virus in mink cells. (14 refs)

- 79-2255 Studies of an RNA Virus Isolated from a Human Histiocytic Lymphoma Cell Line.** (Eng) Kaplan, H. S. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305). *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 695-706; 1978.

The characteristics and infectivity of a C-type RNA virus isolated from a permanent cell line (SU-DHL-1) established from a patient with diffuse histiocytic lymphoma (DHL) were studied. The SU-DHL-1 virus has many of the characteristics of other mammalian C-type RNA viruses: endogenous reverse transcriptase (RT) activity inhibitable by antibodies to subhuman primate viral RT's, the capacity to induce syncytia in rat XC cells, and typical electron microscope morphology. The supernatant culture fluids of 4/7 other histiocytic lymphoma cell lines assayed contained significantly elevated levels of RT-like activity. One of these cell lines, SU-DHL-2, also induced typical syncytia when cocultivated with rat XC cells. The virus was noninfectious for a spectrum of human and other mammalian normal and neoplastic cells of nonhematopoietic origin, but it readily infected another human malignant lymphoma cell line, SY-AmB-3, established from a patient with North American Burkitt's lymphoma. After infection, SY-AmB-3 cells revealed the presence of cytoplasmic viral antigens by indirect immunofluorescence, released sustained high levels of RT-like activity into the supernatant culture fluids, and acquired the capacity to induce syncytia when cocultivated with rat XC cells. Human

and rhesus monocytes and possibly human B, but not T, lymphocytes exhibited unusual changes in their growth behavior in vitro following infection with the SU-DHL-1 virus, as well as morphologic and cytogenetic abnormalities. The biological significance of these changes is not yet known. (34 refs)

- 79-2256 Human Hematopoietic Cells: A Search for Retrovirus-related Information in Primary Tissues and Development of Liquid Suspension Culture Systems for Studies of Cell Growth and Differentiation and of Virus-Cell Interactions.** (Eng) Gallo, R. C. (Lab. Tumor Cell Biology, NCI, Bethesda, MD, 20014); Gallagher, R. E.; Ruscetti, F. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 671-694; 1978.

Studies examining primary human hematopoietic tissues for the presence of retrovirus information and the development of liquid suspension culture systems for human hematopoietic cells are reviewed. Available data indicate that humans have endogenous viral genes. Several investigations are consistent with the idea that tissues from some leukemia-lymphoma patients contain acquired viral information: antibodies in sera from leukemic patients reacted with the reverse transcriptase from some of the C-type primate viruses, and molecular hybridization has revealed sequences in the DNA from a few leukemic patients that were homologous with sequences in murine or primate C-type viruses. C-type virus production has been observed in only 1/38 lines of myelogenous leukemia cells that actively replicated in liquid suspension culture for 6 wk. Human T lymphocytes and myeloid cells were grown in liquid suspension culture, and a human myeloid cell line was established in which the cells maintained a stable promyelocyte morphology. Most types of blastic WBC cultures were readily infected by primate C-type viruses, but continuously replicating, differentiated T-cell strains, short-term cultures of differentiated myeloid cells, and two blastic Epstein-Barr virus (EBV)-negative lines were not susceptible to productive infection. Other studies of the infection of human WBC with C-type viruses suggest that the effect of the C-type viral infectivity procedures may be mediated if the transforming effect of EBV is promoted. - 79-2259 Fanleaf of Vine Plants and the Etiology of Cancer.** (Fre) Bosc, M. (Laboratoire d'Histologie, Institut Bouisson-Bertrand, 5 rue Ecole-de-Medecine, 34000 Montpellier, France). *Trav Soc Pharm Montp* 38(3): 221-235; 1978.

The biochemical characteristics of fanleaf, a viral disease of vine plants, and cancer are compared. The vegetative organs of vine plants affected by fanleaf are characterized by intense glycogenesis and the absence of polyphenols, whereas anaerobic glycolysis and the presence of polyphenols are typical traits of tumor tissues. The anaerobic glycolysis in tumor tissues is linked with the appearance of pyruvate kinase isoenzymes. Unlike the situation in tumor tissues, tryptophan metabolism is inhibited in the diseased vine plants. The enzymatic differences between cancer and fanleaf suggest that the latter may be useful as a model for studying enzymatic mechanisms capable of repressing tumor growth. (15 refs)

- 79-2260 In Vitro Transformation of Cultured Cells from *Nicotiana tabacum* by *Agrobacterium tumefaciens*.** (Eng) Marton, L. (Inst. Plant Physiology, Biological Res. Center, P.O. Box 521, H-6701 Szeged, Hungary); Wullems, G. J.; Molendijk, L.; Schilperoort, R. A. *Nature* 277(5692): 129-131; 1979.

The in vitro transformation of cells from *Nicotiana tabacum* by various strains of *Agrobacterium tumefaciens* was studied. The tobacco cells were mixed with one of the virulent bacterial strains (LBA 4013, LBA 4001, and LBA 305) or one of the nonvirulent strains (LBA 4011 and LBA 301) for 32 hr. The cells were then cultured in medium supplemented with hormones, followed by subculture in medium without hormones. Colonies, which were scored after a 7-wk culture period, were observed only when the tobacco cells were incubated with one of the virulent strains of *A. tumefaciens*. Most of the transformed calli retained the ability to proliferate hormone independently after subsequent passages on hormone-free medium. Some of these calli also demonstrated lysopine dehydrogenase (LpDH) activity. Calli obtained in vivo after wounding and infection of plants with the same virulent bacterial strains always contained both tumor markers, and they retained both markers after cloning and subculturing for > 2 yr. LBA 4013 had the highest transformation

efficiency of the three virulent strains, which might be related to its ability to transmit the tumor-inducing (TI) plasmid to other bacteria in a high frequency. Preliminary results from experiments using purified TI-plasmid DNA as the transforming vehicle indicate that TI DNA alone is sufficient for tumor induction in cultured plant cells. (17 refs)

- 79-2261 Involvement of DNA Gyrase in Replication and Transcription of Bacteriophage T7 DNA.** (Eng) De Wyngaert, M. A. (Dept. Biology, Univ. Rochester, Rochester, NY, 14627); Hinkle, D. C. *J Virol* 29(2): 529-535; 1979.

The effect of coumermycin (CM), an inhibitor of *Escherichia coli* DNA gyrase, on the kinetics of DNA, RNA, and protein synthesis during bacteriophage T7 infection of *E. coli* was investigated using strains resistant (NI 748) and sensitive (NI 747) to CM. Growth of T7 in the CM-sensitive strain was reduced to 20% of the control values at 10 µg/ml CM, whereas growth in the resistant strain was unaffected. The rate of DNA and RNA synthesis was significantly reduced in the presence of CM in NI 747 but not in NI 748. Protein synthesis was also inhibited in the CM-sensitive strain, but not as much as DNA and RNA synthesis. Synthesis of T7 early proteins, the products of genes that are transcribed by *E. coli* RNA polymerase and are expressed immediately after infection, was not affected by CM. Synthesis of many of the late proteins, however, was severely inhibited by CM. It is concluded that *E. coli* DNA gyrase may play an important role in the transcription as well as in the replication of T7 DNA. (26 refs)

- 79-2262 Correlating Terminal Deoxynucleotidyl Transferase and Cell-Surface Markers in the Pathway of Lymphocyte Ontogeny.** (Eng) Silverstone, A. E. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Rosenberg, N.; Baltimore, D.; Sato, V. L.; Scheid, M. P.; Boyse, E. A. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 433-453; 1978.

Evidence is presented that terminal deoxynucleotidyl transferase (TdT) is found in cells developmentally intermediate between the colony-forming units-spleen (CFU-S) and the mature T and B effector cells. The presence of TdT in developing thymocytes but not in circulating T cells is mirrored by its presence or absence in tumor populations of corresponding phenotypes. The more differentiated a T cell becomes, the less TdT it has, and the more differentiated the tumor cell line is with respect to its surface antigens, the less TdT is evident. The tumor cells studied generally had the properties of differentiating cells, such as the Sc-1 antigen, a surface antigen on pluripotent stem cells, TdT, and the thymus-leukemia (TL) antigen. Analysis of human tumors indicated that the major class of acute lymphoblastic leukemia (ALL) has cells with high TdT and a potential relationship to B cells. The occurrence of these human cells encourages a belief that there may be a stage of pre-B cells with a high level of TdT. Normal murine bone marrow contained a small percentage of cells that had very high levels of TdT. About 50% of bone marrow TdT occurred in cells carrying the Lyb-2 alloantigen, a B-cell marker. TdT in normal bone marrow was associated with cell sets carrying Lyb-2 and Sc-1. More than 85% of the total TdT in bone marrow was demonstrated to reside in the 40% or less of cells classified as either prothymocytes (Thy-1 inducible) or Lyb-2 positive. These results indicate that TdT, both in normal cells and tumor cells, appears only in developing cells of the lymphocyte pathway and not in functional cells or tumor homologs of functional cells. - 79-2263 An Immunoregulatory Factor Associated with Spleen Cells from Tumor-bearing Animals. III. Characterization of the Factor's Target Cells.** (Eng) Isakov, N. (Dept. Cell Biology, The Weizmann Inst. Science, Rehovoth 76100, Israel); Hollander, N.; Segal, S.; Feldman, M. *Int J Cancer* 23(3): 410-414; 1979.

The target cell for the activity of an immunoregulatory enhancing factor (EF) associated with spleen cells from tumor-bearing mice was investigated. EF has been found to potentiate the generation of antibody-producing cells. In the present experiment, EF potentiated antibody production only

in adult thymectomized, nude, and B (adult thymectomized mice lethally irradiated and reconstituted with syngeneic fetal liver cells) mice; i.e., those devoid of mature T lymphocytes. Mice were then immunized with sheep RBC (SRBC) as carrier or with chicken RBC coupled to 4-hydroxy-3-iodo-5-nitrophenylacetylazide (NIP-chicken RBC) as a source of NIP-specific primed B cells in the presence or absence of EF. Various combinations of spleen cells from the donor immunized mice were transferred with NIP-SRBC to lethally irradiated recipient mice. EF did not potentiate helper function except when primed B cells were used, whereas a clear activation or clone expansion of hapten-specific B cells was observed. In contrast, a clear activation or clone expansion of hapten-specific B cells was observed. The data indicate that the EF from tumor-bearing animals directly affected the antigenic triggering of B lymphocytes and their subsequent proliferation and differentiation to antibody-producing cells. (15 refs)

- 79-2264 Role of Different T Cell Sets in the Rejection of Syngeneic Chemically Induced Tumors.** (Eng) Shimizu, K. (1st Dept. Internal Medicine, Nagoya Univ. Sch. Medicine, Nagoya, Japan); Shen, F. W. *J Immunol* 122(3): 1162-1165; 1979.

To ascertain the participation of T lymphocytes in the rejection of syngeneic chemically induced tumors, viable dissociated cells of a methylcholanthrene-induced C57BL/6 (B6) sarcoma were combined with peritoneal cells from highly immunized syngeneic B6 donors and inoculated sc into untreated syngeneic B6 mice. Nonadherent immune peritoneal cells (NA.IPC) protected the B6 recipients from progressive tumor growth under these conditions. The protection was against the specific sarcoma against which the donor mice had been immunized and was achieved with NA.IPC:tumor cell ratios of less than 1:4. The protective NA.IPC cells were T cells, as shown by the fact that elimination of the Thy-1(+), Lyt-1(+), Lyt-2(+), or Lyt-3(+) population abolished protection. Treatment of NA.IPC with α -Lyt-1.2 serum abolished protection as a specific result of the elimination of Lyt-1(+) cells. Antigenic specificity for the Lyt-2 and Lyt-3 systems was also shown. Protection by NA.IPC cells could not be restored by combining Lyt-1 and Lyt-23 cell sets selected from the NA.IPC populations. The data are consistent with the hypothesis that cell-mediated cytotoxicity is an exclusive function of Lyt-23:CS (cytotoxicity; suppression) cells and that these, and possibly Lyt-1:H (helper) amplifier cells, are generated during the assay from a specifically primed antecedent Lyt-123:ARC (antigen-reactive celi) cell set. (14 refs)

79-2265 Differentiation of Precursor Cytotoxic T Lymphocytes Following Alloantigenic Stimulation.

(Eng) Sundharadas, G. (Immunobiology Res. Center, Univ. Wisconsin, Madison, WI, 53706); Sopori, M. L.; Hayes, C. E.; Narayanan, P. R.; Alter, B. J.; Bach, M. L.; Bach, F. H. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 519-528; 1978.

Factors required for an optimal cytotoxic response following alloantigenic stimulation were investigated in the mixed-leukocyte culture (MLC) and cell-mediated lympholysis assays. In studies of the effect of MLC supernatant on the generation of cytotoxic T-lymphocytes (Tc), the supernatant of an allogeneic MLC resulted in a very significant expansion of the level of the cytotoxic response whereas the supernatant from a syngeneic MLC had no effect. Results of experiments in which an agar system was used indicate that the precursor Tc must have received other signals, in addition to the cytotoxic-defined (CD) antigen stimulus, for the initiation and expansion of the development of Tc to have occurred. The results also suggested that a normal MLC under the agar layer was capable of producing soluble factors that could diffuse through the agar and provide the additional second signal needed for the development of Tc from precursor Tc. The effects of poly A:U and lipopolysaccharide (LPS) on the development of Tc indicate that LPS and poly A:U may enhance cytotoxic responses by different mechanisms. Poly A:U may only be able to amplify an ongoing cytotoxic response, but LPS may have the capacity to promote the initiation of a cytotoxic response as well as to amplify it. Under the conditions used, poly A:U required the presence of adherent cells for its action, whereas LPS did not, which also suggests that the two agents exert their effect at two different steps in the development of Tc. (12 refs)

79-2266 Murine IgD and B-Lymphocyte Differentiation.

(Eng) Uhr, J. W. (Dept. Microbiology, Univ. Texas Southwestern Medical Sch., Dallas, TX, 75235); Cambier, J. C.; Ligler, F. S.; Kettman, J.; Vitetta, E. S.; Zan-Bar, I.; Strober, S. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 505-518; 1978.

Subsets of B cells were separated on the basis of cell-surface isotype, and their immune function was characterized along with the role of IgM and IgD in the induction of immunologic tolerance and in triggering were determined. Membrane IgD clearly develops late in antigen-dependent B-cell differentiation. The following sequence is proposed: cells bearing only IgM ($\mu+$) acquire IgD, thereby expressing two isotypes ($\mu+\delta+$), and then some of the $\mu+\delta+$ cells lose surface IgM to become cells that bear only IgD ($\delta+$). The IgM receptor alone plays a critical role in the response to thymus-independent (TI) antigens, but both the IgM and IgD receptors are involved in the response to thymus-dependent (TD) antigens. $\gamma+$ cells are also present, and they are involved in producing only IgG responses to TD antigens. Membrane IgD appears to play an important role in the sig-

nal discrimination between tolerance induction and triggering of $\mu+\delta+$ cells. The acquisition of IgD confers resistance to induction of tolerance upon TD antigen-reactive cells but not TI antigen-reactive cells. Since both isotypes are needed to trigger a $\mu+\delta+$ cell, three signals may be needed for stimulation, since T help is also essential. (22 refs)

79-2267 Malignant Transformation of Tracheobronchial Juvenile Papillomatosis Without Prior

Radiotherapy. (Eng) Siegel, S. E. (Div. Hematology-Oncology, Childrens Hosp. Los Angeles, 4650 Sunset Blvd., Los Angeles, CA, 90027); Isaacs, H.; Cohen, S. R.; Stanley, P. *Ann Otol Rhinol Laryngol* 88(2,part 1): 192-197; 1979.

A case of fatal squamous cell carcinoma of the trachea and bronchi developed in a 19-yr-old man who had been previously tracheotomized to relieve obstruction from recurrent laryngeal papillomas. The patient had undergone prolonged tracheotomy and numerous laryngoscopic and bronchoscopic procedures since the age of 4 yr for recurrent laryngeal papillomas. Recurrent tracheal papillomas developed in addition at age 8. Treatment with cytosine arabinoside produced no change in tumor growth; the patient did not receive radiotherapy until the appearance of tracheal and bronchial squamous cell carcinoma 15 yr following the initial diagnosis. Irradiation and systemic and topical chemotherapy were ineffective, and recurrent arterial compromise due to malignant tumor emboli was eventually fatal. The clinical course in this patient indicates that malignant change can occur in recurrent juvenile papillomatosis in the absence of prior radiotherapy. (27 refs)

79-2268 Stimulation of Resistance to Tumor Growth of Athymic Nude Mice Pretreated by Combined

Local Hyperthermia and X-Irradiation. (Eng) Yerushalmi, A. (Radiation Unit, Weizmann Inst. Science, POB 26, Rehovot, Israel); Weinstein, Y. *Cancer Res* 39(3): 1126-1128; 1979.

The contribution of T lymphocytes to the stimulation of resistance against local tumor growth in athymic nude mice of C57BL background pretreated with local hyperthermia (HT) + x-irradiation was studied. Animals were pretreated in the left hind leg by local HT (42.7 for 45 min or 44.5 C for 60 min) and/or local x-irradiation (800 R). Twenty-four hours posttreatment, the animals were inoculated im with 0.5×10^6 metastatic Lewis lung carcinoma cells. Half of the animals in each group were inoculated in the pretreated leg and half were inoculated in the contralateral untreated leg. The life-span of normal and nude mice pretreated by local HT + irradiation was increased 30%-45%. The increase in life-span was similar in animals inoculated in the pretreated leg or in the untreated leg. These results indicate that T lymphocytes are not involved in the protection against tumor growth. (18 refs)

- 79-2269 Characteristics of a Low-Molecular-Weight Factor Extracted from Mouse Tumors that Affects In Vitro Properties of Macrophages.** (Eng) Cheung, H. T. (Immunobiology Res. Center and Dept. Medical Microbiology, Univ. Wisconsin, Madison, WI, 53706); Cantarow, W. D.; Sundharadas, G. *Int J Cancer* 23(3): 344-352; 1979.

The characteristics of a dialyzable low-mol-wt factor extracted from four different induced and spontaneous mouse tumors were studied. In the presence of the dialyzates derived from tumors, macrophages reversed their spreading and reverted to a round morphology. The effect was reversible, and the dialyzates had no apparent sublethal effects on the macrophages. The tumor dialyzates enhanced the migration of complete Freund's adjuvant-induced peritoneal cells out of capillary tubes. The migration of purified macrophages was similarly enhanced. Sodium azide (1 mM) inhibited the migration enhancement by approx 50% without affecting cell viability. The tumor dialyzates significantly inhibited the lipopolysaccharide-induced cytotoxicity of macrophages in a concentration-dependent fashion. Dialyzates from normal tissues had none of the foregoing effects. The macrophage-modulating factor in the tumor dialyzates was shown to be a product and property of the tumor cells per se, and not the tissues surrounding them. Partially purified factor, which retained all of the foregoing effects on macrophages, was not sensitive to heating, pronase, or a mixture of bovine spleen phosphodiesterase II, *Escherichia coli* alkaline phosphatase, and pancreatic ribonuclease. It was lipidlike and soluble in both organic solvents and aqueous media. It had ionizable group(s) and was anionic at neutral pH but nonionic under acid conditions. (27 refs)

- 79-2270 Enhancement of Tumor Outgrowth by Tumor-associated Blocking Factors.** (Eng) Hellstrom, K. E. (Div. Tumor Immunology, Fred Hutchinson Cancer Res. Center, Seattle, WA); Hellstrom, I. *Int J Cancer* 23(3): 366-373; 1979.

The ability of cell-free tumor fluid (TF) from 3-methylcholanthrene-induced BALB/c sarcomas to block antitumor immunity in vitro and to enhance tumor growth in vivo was studied. TF from two sarcomas, 1315 and 1321, decreased the in vitro cytotoxic effect of lymph node cells from tumor-immune, syngeneic donors (BALB/c mice), the blocking activity of these TF being greater than that of sera from tumor-bearing mice. Similar results were obtained with TF from sarcomas 1407 and 1408. The blocking activity was tumor line-specific. TF from sarcomas 1407 or 1408 nonspecifically enhanced the outgrowth of sarcomas 1407 and 1408 inoculated into syngeneic mice. There was also some degree of tumor line-specific enhancement. TF mixed directly with the inoculated tumor cells generally facilitated tumor outgrowth more than did TF given ip. TF prepared from normal spleen tissue did not cause a specific enhancement of 1407 outgrowth. TF from sarcomas 1321 and 1410 also enhanced 1321 and 1410 sarcoma outgrowth, with TF from the same

tumor enhancing slightly better than that from a different tumor. TF from sarcomas 1315 and 1321 given ip inhibited the growth of both sarcomas in vivo. (21 refs)

- 79-2271 Incapacity of Hematopoietic Stem Cell-deprived Mice to Produce Tumor Colonies Induced by Friend Virus-infected Cells.** (Eng) Wendling, F. (I.N.S.E.R.M. U.22, Institut du Radium, Batiment 110, Faculte des Sciences Paris-Sud, 91405 Orsay, France); Tambourin, P.; Moreau-Gachelin, F. *Exp Hematol* 6(10): 777-784; 1978.

The role of host hematopoietic stem cells in the formation of tumor colonies in the spleen of (C57BL/6 x DBA/2) F1 mice given grafts of spleen cells from polycythemia-inducing Friend virus (FVP)-infected DBA/2 donors was investigated. Hematopoietic stem cell compartments of recipient mice were destroyed by Myleran (busulfan) treatment or γ -ray irradiation. A single injection of Myleran (40 mg/kg, intragastrically) reduced the the number of pluripotent hematopoietic stem cells and erythropoietin-responsive cells (ERC) in polycythemic mice to around 1% of that of controls. Repeated injections of erythropoietin (EPO) restored the ERC population. Pretreatment of polycythemic hosts with Myleran totally suppressed the colony-forming ability of grafted FVP-infected spleen cells, but it had no effect on the colony-forming ability of grafted tumor cells isolated from a leukemic DBA/2 mouse 43 days after FVP infections. When Myleran-treated recipients were inoculated with EPO, spleen colonies were formed, and the number of colonies formed was similar to that in control mice. Similar results were obtained in hosts whose ERC populations were damaged by irradiation. These data strongly suggest that spleen colonies result from the proliferation of host cells transformed by virus released by FVP-infected cells and not from the proliferation of donor tumor cells. (29 refs)

- 79-2272 Natural Cytotoxicity--An Analysis of Effector Cells. The Role of the Fc Receptors.** (Eng) Kristensen, E. (Fibiger Lab., Ndr. Frihavnsgeade 70, DK-2100 Copenhagen O, Denmark); Langvad, E. *Cancer Immunol Immunother* 5(2): 71-76; 1978.

The microcytotoxicity assay was used to examine lymphocyte subpopulations derived from healthy donors and persons suffering from nonmalignant diseases for natural cytotoxicity (NC). Non-T lymphocytes exerted a significantly greater cytotoxicity against the established melanoma line RPMI 7931 than did T lymphocytes. The cytotoxicity of the non-T lymphocytes was dependent on the lymphocyte/target cell ratio. Both T and non-T lymphocytes showed little NC toward short-term target cell cultures. The cytotoxicity of non-T lymphocytes was enhanced by enrichment with Fc receptor-bearing (Fc R-positive) cells and reduced by depletion of R-positive cells; these cells above showed a high level

of NC. IgG split products, comprising the Fc portion of the molecule, and IgG immune complexes decreased the NC of Fc R-bearing non-T cells. The cells responsible for the increase in NC of T cells treated with IgG split products were associated with the Fc R-negative fraction. Monocytes contaminating the T-lymphocyte fraction were not involved in enhanced T-cell cytotoxicity. The F(ab')₂ immunoglobulin fragments had no effect on NC. The data indicate that most NC is expressed by cells belonging to the Fc R-bearing non-T fraction. (23 refs)

79-2273 A Specific Helper Factor Which Enhances the Cytotoxic Response to a Syngeneic Tumour.

(Eng) Kilburn, D. G. (Dept. Microbiology, Univ. British Columbia, Vancouver, British Columbia, Canada V6T 1W5); Talbot, F. O.; Teh, H. S.; Levy, J. G. *Nature* 277(5696): 474-476; 1979.

The isolation of a helper factor that specifically enhances the generation of cytotoxic cells in a syngeneic mouse tumor system is reported. The helper factor was prepared from a single splenic fraction obtained from 8-day tumor-bearing mice. The generation of cytotoxicity to syngeneic P815 mastocytoma cells was enhanced markedly at a concentration of 0.005 to 0.05 spleen equivalents. In addition, the purified factor increased the cytotoxicity of a normal (control) factor about fourfold in terms of cytotoxic units. The factor was specific for the syngeneic tumor system and was T-cell-dependent. It was coded for by the I region of the major histocompatibility complex and it bound antigen. However, although it bore I-region-coded markers, it did not possess constant-region determinants of mouse immunoglobulin. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis of iodinated factor indicated that it is a monomer with a mol wt of 65,000. This factor may offer a means of altering tumor growth in vivo. (17 refs)

79-2274 Phytohaemagglutinin (PHA)-induced Cytotoxicity. II: The Effect of PHA-Stimulated Spleen Cells on Ehrlich Ascites Tumor Cells in Mice. (Jpn) Aoki, S. (Dept. Urology, Sch. Medicine, Keio Univ., Tokyo, Japan). *Jpn J Urol* 69(11): 1404-1411; 1978.

The effect of phytohemagglutinin (PHA)-stimulated mouse spleen cells on Ehrlich ascites tumor (EAT) cells was studied in ddY mice. The ³H-thymidine uptake of the spleen cells was enhanced by PHA stimulation (ratio of stimulated:unstimulated uptake was 27.5), as was the cytotoxicity (⁵¹Cr-release assay) of the spleen cells to the EAT cells (mean value at an effector/target cell ratio of 100:1 was 9.72%). Administration of PHA-stimulated spleen cells and EAT cells to the mice ip or sc produced antitumor effects. With the sc route, the tumor incidence was 1/4, vs 4/4 for mice inoculated with tumor cells alone and 4/4 for mice inoculated with tumor cells and untreated spleen cells from tumor-bearing

ers. The high rate of tumor formation in mice inoculated with the latter suggests the presence of suppressor T cells. Treatment by the ip route was accompanied by marked inflammatory changes of the visceral peritoneum that may have been induced by chemical mediators formed in the tumor-lymphocyte reaction. (31 refs)

79-2275 Phytohemagglutinin (PHA)-induced Cytotoxicity. III: Cell-mediated Immunoresponsiveness in Genitourinary Cancer Patients. (Jpn) Aoki, S. (Dept. Urology, Sch. Medicine, Keio Univ., Tokyo, Japan). *Jpn J Urol* 69(11): 1412-1421; 1978.

The phytohemagglutinin (PHA)-induced cytotoxicity of the peripheral blood lymphocytes (PBL) from 32 genitourinary cancer patients and 13 normal subjects against HeLa cells was compared. Among the patients there were 9 cases of bladder cancer, 6 prostatic carcinomas, 5 renal cell carcinomas, 4 renal pelvic tumors, 3 testicular carcinomas, 2 ureteral tumors, 2 uterine carcinomas, and 1 urethral carcinoma. The PHA-induced cytotoxicity of the patient PBL was decreased significantly compared with that of the control PBL, especially in patients with advanced renal cell carcinoma. Periodic tests of all patients showed that cytotoxicity decreased as the cancer progressed. The degree of PHA-induced blastoid transformation of the patient PBL was also reduced, and it correlated with the PHA-induced cytotoxicity. In addition, the number of PBL was decreased in the patients. However, this decrease plus the high RBC sedimentation rate value and the high α_1 -globulin, α_2 -globulin, and fibrinogen levels found in this group did not significantly correlate with the decreased PHA-induced cytotoxicity and blastoid transformation of their PBL. 79-2276 Is Antibody-dependent Cellular Cytotoxicity an Important Mechanism of Resistance to Tumors In Vivo? (Eng) Cavallo, G. (Istituto di Microbiologia, Univ. Torino, Via Santena 9, 10126 Turin, Italy); Giovarelli, M.; Forni, G.; Landolfo, S. *Immunochimistry* 15(10/11): 801-805; 1978.

The effect of passive administration of heterologous antibody before tumor challenge was investigated in adult and newborn BALB/c mice. Adult mice preinjected once or twice with absorbed rabbit antibody to mammary adenocarcinoma ADK-1t IgG showed a decrease in ADK-1t tumor takes of 60% and 80%, respectively, compared with controls preinjected with absorbed normal rabbit IgG. In newborn mice, heterologous antibody treatment resulted in only an initial delay of tumor growth, and there was no significant difference in final tumor incidence. No differences in tumor growth and final incidence were observed in mice preinoculated with normal or ADK-1t immune rabbit IgG and challenged with sarcoma cells. The absorbed antibody showed a single precipitation band in agar gel. It is concluded that the pres-

ence in the first phases of the tumor-host relationship of heterologous tumor-specific antibody can drastically enhance host resistance to a spontaneous, poorly immunogenic tumor. The antibody activity appears to be mediated by complex interactions with the multifactorial system of host reactive mechanisms. The results of this and other studies suggest that anti-tumor-specific humoral antibody might constitute a potent tool in the immunotherapy of neoplasia. (31 refs)

- 79-2277 Differences in Antibody Fixation on SV40-transformed Cells in the Presence and Absence of Complement.** (Fre) Duthu, A. (Laboratoire d'Immunochimie virale, Institut de Recherches Scientifiques sur le Cancer, B.P. No. 8, F94800 Villejuif, France); de Vaux Saint Cyr, C. *Bull Cancer (Paris)* 66(1): 17-24; 1979.

The fixation of antibodies directed against virus-induced antigens on simian virus 40-transformed Syrian hamster fibroblasts (TSV,Cl₂) was studied during incubation of the cells in sera from tumor-bearing hamsters in the presence or absence of guinea pig complement. Antibody fixation was revealed by an anti-hamster immunoglobulin immune serum labeled with ¹²⁵I. Autoradiographic observations were made by light and electron microscopy. Cells incubated with antibodies alone were labeled evenly on the plasma membrane, and there was no decrease in total cell population compared with controls. When the cells were incubated in complement-containing sera, one cell subpopulation was labeled heavily, and these cells detached from the flask and were destroyed. After 11 hr of incubation, about one-fifth of the cells still attached to the flask were labeled heavily, but the others were not labeled. The findings indicate the protective action of antibodies toward tumor cells when complement is absent or inactive in vivo. (23 refs)

- 79-2278 Genetic Control of Responsiveness to the Tumor-associated Transplantation Antigen of a Chemically Induced Murine Fibrosarcoma.** (Eng) Parmiani, G. (Div. Experimental Oncology A, Istituto Nazionale per lo Studio e la Cura dei Tumori, Via G. Venezian 1, 20133 Milano, Italy). *Immunogenetics* 7(3): 271-275; 1978.

A possible genetic basis for strain differences in the immune response to a methylcholanthrene-induced transplantable fibrosarcoma (C-1) was investigated in hybrid mice. BALB/c/Dp (C) females, which were not resistant to the tumor and carried the *H-2k* haplotype, were bred to unresponsive BALB/c x C3Hf/Dp (CC3) males, which carried the *H-2d* haplotype. On challenge with 10⁵ C-1 cells, 18/22 mice with the *H-2d/d* haplotype were tumor-resistant, whereas 18/20 mice with the *H-2d/d* haplotype developed tumors. Immunity to the individual tumor-associated transplantation antigens (TATA) of C-1 was found predominantly among mice with the *H-2d/k* genotype. Hy-

brids between C and the congenic BALB.B (*H-2b*) mice developed anti-TATA immunity. Hybrids between C mice and recombinant strains of background A (which contained different subregions of the *H-2k* haplotype) showed 34%-94% protection against tumor challenge. The results indicate a genetic control over in vivo immunity to the individual TATA of C-1. The control appears to be polygenic, in that both the dominant gene(s) mapping in the I region of the major histocompatibility complex (MHC) and apparently governing the unresponsive trait, as well as non-H-2 genes, which possibly counteract the effect of the MHC gene(s), seem to be involved. (14 refs)

- 79-2279 Transplantability of Ferridextran-induced LEW/CUB Tumours, FLA, FLB, FLC, and FL.** (Eng) Kren, V. (Dept. Biology, Faculty General Medicine, Charles Univ., Prague, Czechoslovakia); Kršáková, M.; Bila, V. *Folia Biol (Praha)* 24(6): 389-390; 1978.

The transplantability of four ferridextran-induced tumors (FL, FLA, FLB, and FLC) was examined in syngeneic LEW recipients and in LEW congenic hybrids. In the syngeneic animals, the transplantability of the four tumors was almost 100%. In the congenic hybrids, the only tumor to cross the H-1 barrier was FLB, which killed a female LEW.1A x LEW.1D recipient. However, the FLA and FLB tumors killed 100% of intact H-4 and H-5 congenic recipients, ie, LEW.C-4A and LEW.1x-5P. The FLC tumor killed 11/12 LEW.C-4A recipients but only 11/24 LEW.1x-5P recipients. Although FLA, FLB, and FLC were all rejected by LEW.C-4A recipients primed with FL tumor cells, the tumors killed, respectively, 19/23, 8/22, and 4/17 primed LEW.1x-5P recipients. It is suggested that the differences in cell surface properties of tumors could be responsible for their different abilities to cross some alloantigenic barrier or to be rejected. (5 refs)

- 79-2280 Determination of Plasma Levels of Carcinoembryonic Antigen by Two Methods.** (Jpm) Murata, K. (Central Clinical Lab., Kansai Medical Univ. Hosp., Kansai, Japan); Fujiwara, H.; Kan, Y. *Gan No Rinsho* 25(2): 107-114; 1979.

The determination of plasma levels of carcinoembryonic antigen (CEA) by the double antibody (DA) method and the solid phase (SP) method was compared. The DA method was superior with respect to reproducibility, stability after long-term freeze storage, and accuracy. The average recovery values were 102.3% for the DA method and 78.5% for the SP method. However, the DA method was more complicated and less convenient than the SP method. In normal subjects, the CEA levels were found to be < 10 nanograms (ng)/ml. Six patients with cancers at various sites had levels > 10 ng/ml; patients with benign tumors also had abnormally high levels of CEA. (10 refs)

- 79-2281 The Immune Response of (C57BL/6 x C3H)F₁ Mice to the Endogenous AKR-MuLV.** (Eng) Ihle, J. N. (Basic Res. Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Lee, J. C. *Med Microbiol Immunol (Berl)* 164(1/3): 207-216; 1977.

The humoral and cellular immune response of (C57BL/6 x C3H)F₁ mice to the endogenous AKR murine leukemia virus (MuLV) was characterized. The data clearly indicated the existence of an intact immune response against the virus. Antibodies specifically directed against the envelope glycoprotein gp71 and the envelope protein component p15(E) were present in all mice after 3 mo of age, and they constituted a chronic lifelong immune response. The antibody against gp71 was type-specific, and the IgG antibodies could mediate complement-independent neutralization of virus infectivity. The antibodies against p15(E) were group-specific and did not neutralize virus infectivity. Spleen cells from 6-wk-old mice were specifically cytotoxic against an AKR MuLV-producing tumor cell line but not against two nonproducing fibroblast cell lines. This cytotoxicity could be blocked with AKR MuLV gp71 or intact virus, but not with Rauscher leukemia virus (RLV) gp71 or RLV. Killing was shown to be mediated by null cells and by T cells capable of responding to gp71 in vivo and of being induced in vitro. In experiments designed to assess the consequences of the expression of endogenous viral antigens, the growth of virus-positive tumors in immune-positive mice was significantly less than that of virus-negative tumors in either immune-positive or -negative mice. These data suggest that the coupled expression of viral antigens with transformation in immune-responsive mice may actually contribute to tumor regression. (17 refs)

- 79-2282 Microenvironmental Influences on Granulopoiesis in Acute Myeloid Leukemia.** (Eng) Greenberg, P. (Dept. Medicine, Veterans Adm. Hosp., Palo Alto, CA, 94304); Mara, B. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book A), 528 pp.; 405-409; 1978.

Marrow cell-derived colony-stimulating activity (CSA) levels in normal subjects and in patients with acute myeloid leukemia (AML) were assayed. In normal subjects, all of the CSA was provided by the adherent cell population. It was found that 84%-87% of the adherent marrow CSA-producing cells were α -naphthyl acetate esterase positive, resembled monocytes morphologically and were capable of phagocytosing latex particles. This suggests that middensity monocytes and macrophages contribute a major portion of the marrow CSA. Thirteen of 21 patients with AML had significantly low marrow CSA levels at diagnosis or relapse. Only 4/13 patients with low marrow CSA entered complete remission, whereas 7/8 patients with normal CSA did. Four patients in partial remission and 42/46 in complete remission had normal marrow CSA values. In contrast, low or progressively decreasing marrow CSA values occurred in patients with impending relapse. Marrow CSA values paralleled marrow granulocytic progenitor cells (colony-forming units--culture,

CFU-C) during remission until relapse, with normal CSA values persisting longer than CFU-C. The monitoring of marrow CSA provision appears useful for evaluating microenvironmental influences and intramedullary cellular interactions on granulopoiesis and for assessing prognosis and clinical status in AML. (30 refs)

- 79-2283 Introduction.** (Eng) Lennert, K. (Dept. General Pathology and Pathologic Anatomy, Univ. Kiel, Kiel, W. Germany). *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 807-809; 1978.

A section of the Cold Spring Harbor Conference on Cell Proliferation concerning malignant lymphomas is introduced. The hematopoietic stem cell gives rise to many variants of T and B lymphocytes that are separated according to differentiation and function and defined by their morphology and immunologic markers. Each type of cell may be involved in one or more types of malignant lymphoma. Every tumor is derived from B or T cells or is not identifiable as B- or T-cell derived (null cell lymphoma). (2 refs)

- 79-2284 An Immunologic Approach to Classification of Malignant Lymphomas: A Cytokinetic Model of Lymphoid Neoplasia.** (Eng) Lukes, R. J. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90033); Lincoln, T. L.; Parker, J. W.; Alavaikko, M. J. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; pp. 935-952; 1978.

The immunologic approach of the Lukes-Collins (L-C) classification of malignant lymphomas (ML), which relates their morphologic features to findings of modern immunology, is described. In this approach lymphoma cells are regarded as defective immune cells that frequently arise in abnormal immune processes and migrate, target, and function in a manner similar to that of their normal counterparts. The classification is based on the concepts that ML principally involve the T-, B-, and undefined (U)-cell systems and that they commonly develop as a block or switch-on (derepression) of lymphocyte transformation. Because the L-C classification follows the transformation sequence of T and B cells, particularly follicular center cells, it lends itself to cell kinetics studies. Preliminary studies of representative non-Hodgkin's lymphomas, in which both flow cytometry and microfluorometry were used, demonstrated a relationship between cell size, DNA content, and cycle time. The L-C classification led to characteristic DNA-content curves for specific tumor cell populations. The lymphoma cells were demonstrated to be hyperdiploid in DNA content, a finding that, in the future, may allow active benign proliferations to be distinguished from malignant ones. (28 refs)

- 79-2285 Analysis of the Biosynthesis of T25 (Thy-1) in Mutant Lymphoma Cells: A Model for Plasma Membrane Glycoprotein Biosynthesis.** (Eng) Hyman, R. (Dept. Cancer Biology, Salk Inst. Biological Studies, San Diego, CA, 92112); Trowbridge, I. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 741-754; 1978.

Techniques for isolating mutant murine lymphoma cells that show specific defects in the expression of a membrane protein (T25) that carries the Thy-1 alloantigenic determinant are reviewed. Thy-1 mutants have been isolated primarily by cytotoxic immunoselection against allospecificity on cloned Thy-1+ tissue culture-adapted lymphomas. All of the mutants show concomitant loss of the entire T25 molecule from the cell surface. Five complementation classes have been identified; four of them (A, B, C, and E) probably have defects in genes other than the structural gene coding for the Thy-1 alloantigenic difference. The defect in the class-D mutant, however, is in the structural gene coding for the Thy-1 alloantigenic specificity. Biosynthetic labeling experiments demonstrated that all complementation classes except class D synthesize an altered T25 molecule. Pulse-chase experiments and electron microscopy showed that T25 accumulates inside the mutant cells instead of reaching the cell surface and is subsequently degraded. Glycopeptides from T25 molecules of classes A, C, and E mutants do not contain the complex of oligosaccharides found on wild-type cells. In addition, the simple oligosaccharides of the T25 glycoprotein in the class E mutant are smaller than those of the T25 glycoproteins of the other mutants and the wild-type cells. Studies of the expression of Thy-1 in lectin-resistant lines support the hypothesis that defects in the biosynthesis of the oligosaccharide units of T25 can cause the loss of Thy-1 expression on the cell surface. (65 refs)

- 79-2286 Incidence and Pathological Features of Spontaneous Tumors in Athymic Nude Mice.** (Eng) Sharkey, F. E. (Dept. Pathology, Milton S. Hershey Medical Center of Pennsylvania State Univ., Hershey, PA, 17033); Fogh, J. *Cancer Res* 39(3): 833-839; 1979.

The incidence of histopathological features of spontaneous tumors arising in 1,141 athymic nude mice over a 26-mo period were studied. Twenty-four spontaneous tumors (2.1%) were identified, 22 of them arising in the 324 mice that survived for 5 mo or more. Eighteen of the tumors were of the lymphoma-leukemia variety, with six tumors corresponding to Dunn's reticulum cell neoplasm type A. Transplantation of the spontaneous tumors to other nude mice was successful in 3/5 cases. Mice receiving transplants of human colon adenocarcinomas or urogenital tumors developed spontaneous tumors more often than did mice receiving other human tumor transplants. Progressive growth of the human tumor transplants occurred significantly less often in the mice that eventually developed spontaneous tumors than in the mice that showed no spontaneous tumor development. Nevertheless, the incidence of spontaneous tumors in these

mice was similar to that reported for the thymus-bearing Swiss background strain. (16 refs)

- 79-2287 The Evolution of Immunoblastic Lymphomas in Morphologically Nonneoplastic Immunoproliferative Diseases.** (Eng) Rappaport, H. (Dept. Anatomic Pathology, City of Hope Natl. Medical Center, Duarte, CA, 91010); Pangalis, G. A.; Nathwani, B. N. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 877-895; 1978.

The development of malignant lymphoma in two initially nonneoplastic immunoproliferative disorders, intestinal α -chain disease (α -CD) and angioimmunoblastic lymphadenopathy (AILD), is reported. The immunoperoxidase technique was applied to fixed-tissue sections of three cases of intestinal α -CD. Both the plasma cells of the diffuse infiltration and the tumor immunoblasts were strongly positive for α -chains and negative for other chains tested. Forty-two patients with AILD were compared with 36 patients with AILD plus immunoblastic lymphoma (AILD + IL). Patients with AILD tended to respond better to prednisone or to chemotherapeutic agents than patients with AILD + IL. Complete remissions occurred in 63% of the AILD patients, vs 26% of the AILD + IL patients. The median survival was longer for patients with AILD. Malignant lymphoma was evident at autopsy in 20% of the patients with AILD group and 82% of those with AILD + IL; and extranodal involvement by malignant lymphoma at autopsy was observed much more often in the AILD + IL cases. The results indicated that malignant lymphoma can develop in AILD patients after latent periods of unpredictable duration. In AILD, the observations suggest a process of dedifferentiation, since the neoplastic immunoblasts have a diminished capacity for forming immunoglobulins. (47 refs)

- 79-2288 Membrane Phenotypes of Human Leukemic Cells and Leukemic Cell Lines: Clinical Correlates and Biological Implications.** (Eng) Greaves, M. (Membrane Immunology Lab., Imperial Cancer Res. Fund Labs., Lincoln's Inn Fields, London WC2A 3PX, England); Janossy, G.; Francis, G.; Minowada, J. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 823-841; 1978.

Results of screening 1,000 untreated or relapsed cases of leukemia and a substantial number of treated cases with newly developed antisera to acute lymphoblastic leukemia (ALL) are reported. The anti-ALL were applied in parallel with a panel of differentiation-linked membrane markers and two enzymes, terminal deoxynucleotidyl transferase (TdT) and hexosaminidase isoenzyme (Hex). Anti-ALL antibodies reacted with leukemic cells from a proportion (but not all) of patients in three groups: ALL, acute undifferentiated leukemia, and Ph¹-chromosome-positive chronic myelocytic leu-

kemia (CML) in blast crisis. In ALL, strong positivity with anti-ALL was restricted to those patients whose leukemic cells were unreactive with T- and B-lymphocyte markers, ie, null-type (non-T, non-B) ALL. Using anti-ALL and other membrane markers, acute leukemias were dissected into several subclasses that have prognostic significance. The major division within ALL is between the groups designated Thy-ALL and common ALL, which have substantially different prognoses. In a group of > 90 leukemic children followed for up to 4 yr, positive reactions with anti-ALL identified a major subgroup of ALL that has a highly favorable prognosis. In a series of 26 adult anti-ALL-positive patients followed for 2 yr, 2 relapsed: in 1 of these, reemerging leukemic cells were detected immunologically 2 mo ahead of clinical and hematological relapse. It is suspected that both ALL and Ia-like antigens, as well as TdT, are normal gene products of the target cells for acute leukemia transformation and that they may play an important role in early (normal) hematopoiesis. (56 refs)

- 79-2289 Hodgkin's Disease and Anergy.** (Eng) Shifan, T. A. (Div. Hematology and Oncology, Dept. Medicine T-006, Univ. California, San Diego, La Jolla, CA, 92093); Mendelsohn, J. *Blut* 38(1): 1-7; 1979.

A new hypothesis for the pathogenesis of Hodgkin's disease based on the clinical, histologic, and immunologic features of the disease is presented. According to this hypothesis, viral infection of a lymph node cell leads to a vigorous but ineffective immune response. The virus-transformed cells then proliferate and antigenically stimulate the immune system. Host T cells are activated to proliferate, resulting in lymphokine production, B-cell activation leading to immunoglobulin synthesis, and transient regulatory suppression of T-cell activation by other antigens. Specific cellular cytotoxicity to the transformed cells is ineffective, allowing the transformed cells to remain viable and to continue to provide antigenic stimulation. The result is chronic lymphokine production and, in turn, pleomorphic infiltration of proliferating reactive lymphocytes, plasma cells, eosinophils, and macrophages around the transformed infected cells. B-cell activation might also persist with chronic stimulation, and thus occasional hypergammaglobulinemia may develop. The chronic antigenic stimulation leads to chronic rather than transient suppression of the immune response to other antigens, resulting in clinical anergy. Genetic factors might also play a role in the cellular immune response. (29 refs)

- 79-2290 Tumor Acceptance Modified by Passage in Hybrids with Graft-Versus-Host Reaction.** (Eng) Jacobs, B. B. (Life Sciences Center, Nova Univ., 3301 College Ave., Fort Lauderdale, FL, 33314); Parks, R. C. *Exp Hematol* 6(10): 785-790; 1978.

A graft-vs-host reaction (GVHR) was produced in adult F₁

hybrids of DBA/1 (D1), BALB/c (C), and C57BL/6 (B6) mice by an injection of 10⁶ parental strain spleen cells; and 8 days later, the hybrids were challenged with an allogeneic third-party tumor. The BALB/c Leydig cell tumor C4092, the C57BL/6 sarcoma 30795, and the DBA/1 melanoma S91 often grew progressively in B6D1F₁, CD1F₁, and B6CF₁ hybrids or their reciprocal hybrid recipients, respectively, when a GVHR had been induced in these animals. Control hybrids without a GVHR always rejected the tumor. The C4092 tumor was serially transplantable in untreated hybrids after its initial passage in unrelated GVHR-treated mice; the S91 tumor grew in its first passage into untreated B6CF₁ mice but thereafter was rejected by these hybrids; the B6 tumor 30795 grew progressively only in the initial GVHR-treated CD1F₁ or reciprocal hybrids. The reduced immunogenicity of tumors resulting from their passage in unrelated recipients immunosuppressed as a result of a GVHR is comparable to allograft adaptation achieved by techniques such as organ culture pretreatment and presents an additional method for attenuating the rejection of allotransplants. - 79-2291 Kaposi's Sarcoma in Organ Transplant Recipients. Report of 20 Cases.** (Eng) Penn, I. (Dept. Surgery, Univ. Colorado Sch. Medicine, Denver, CO, 80220). *Transplantation* 27(1): 8-11; 1979.

The incidence of Kaposi's sarcoma (KS) among organ transplant recipients is reported. Among 604 recipients who developed 630 de novo malignancies after transplantation, 20 developed KS. All 20 had received renal transplants from malignancy-free donors. Among the general population of the US, KS comprises only 0.6% of all cancers. The average of the recipient KS patients was 42 yr at the time of transplantation, and KS appeared an average of 16 mo after transplantation. In contrast to the general heavy male preponderance of KS, the male:female ratio in this series was only 2.3:1. All patients had been treated with substantial quantities of immunosuppressive drugs, and 11 had received local radiation therapy to the homograft. At least six patients had had herpes simplex virus infections prior to the appearance of KS. One KS recipient also developed a reticulum cell sarcoma of the brain and another developed a carcinoma in a colonic polyp. Eleven of the patients had benign KS, and nine had the malignant variety with involvement of the internal viscera. Four of the 11 patients with benign lesions died from infection and 8/9 patients with malignant disease died from the malignancy. (20 refs)

- 79-2292 Immunological Investigations of Carcinoma of the Cervix.** (Eng) Tilz, G. P. (Medizinische Universitätsklinik, Auerbruggerplatz, A-8036, Graz, Austria); Buffe, D.; Rimbaut, C.; Pickel, H. In: *Cervical Pathology and Colposcopy. Selected Papers from the Second World Congress of Cervical Pathology and Colposcopy held in Graz, Austria, 15-18 October 1975*. Burghardt, E.; Holzer, E.; Jordan, J. A.,

eds. (Stuttgart: Georg Thieme Publishers): 146 pp.; 88-97; 1978.

Immunological testing was performed on first-admission patients with cervical carcinoma before any form of treatment was initiated. No evidence of tumor-specific antigen was found. Patients with advanced cervical carcinoma were immunodepressed, and the degree of immunosuppression correlated with the stage of the disease. Studies of tumor-associated antigens showed no correlation of α_1 -fetoprotein with carcinoma of the cervix. The tumor-associated antigen α_1 -H-globulin correlated well with the evolution of malignancy and seems to be a very useful tool for following patients under treatment. Modification of serum proteins was less impressive than that observed in gastrointestinal lesions and consisted of a diminution of albumin and the esterases and an increase of IgA, ceruloplasmin, and the slow-migrating lipoproteins. Amino acid mapping analyses showed that amino acid levels increased as the cervical carcinoma progressed in nearly all cases. Leucine was particularly prominent. (28 refs)

- 79-2293 HLA and Testicular Cancer.** (Eng) DeWolf, W. C. (Sidney Farber Cancer Inst., Harvard Medical Sch., Boston, MA, 02115); Lange, P. H.; Einarson, M. E.; Yunis, E. J. *Nature* 277(5693): 216-217; 1979.

Tissue typing results are presented for 61 patients with testicular cancer. Thirty patients had seminoma, 27 embryonal cell carcinoma, 26 teratocarcinoma, and 7 choriocarcinoma.

All patients had completed treatment and were clinically free of disease at the time of testing. The antigen frequency of the human major histocompatibility complex (HLA) determinant Dw7 (HLA-Dw7) was significantly increased in the teratocarcinoma group (12/26) compared with that in normal controls (14/150). This difference was not detected in the other patient groups or in the group as a whole. The association between HLA and testicular teratocarcinoma is of interest considering the homology between the major histocompatibility complex of the mouse (H-2) and HLA and the relationship between teratocarcinoma and H-2 in the mouse. PATHOGENESIS

79-2294 Translocation 8;14 in an Ataxia Telangiectasia-derived Cell Line. (Eng) Jean, P. (Laboratoire de cytogénétique, Département d'anatomie, Université de Montréal, Montréal, Canada H3C 3JC); Richer, C. L.; Murer-Orlando, M.; Luu, D. H.; Joncas, J. H. *Nature* 277(5691): 56-58; 1979.

Phytohemagglutinin-stimulated peripheral blood lymphocytes from a 17-yr-old boy with ataxia telangiectasia (AT), a cell line (CB-1) established from his blood lymphocytes and transformed in vitro with Epstein-Barr virus (EBV), a cell line derived from normal cord blood transformed by EBV (Cb 8-11), and a Burkitt's lymphoma (BL)-derived cell line were analyzed by R banding. No significant chromosomal abnormalities were observed in the metaphases from the peripheral blood WBC of the AT patient. However, the CB-1 line showed three different abnormalities, the first two of which were present in all metaphases examined: a translocation t(8q; 14q+), a metacentric marker the size of an X chromosome with a large dark band just above the centromere, and a trisomy 21. The first two abnormalities closely resembled those seen in BL-derived cell lines, BL tumor cells, and other lymphomatous cells. In the control cell line Cb 8-11, chromosomes 8, 14, and 21 were normal, and no metacentric marker was seen. Although the AT patient had no features of the trisomy 21 syndrome, two first-degree cousins of his father had children with Down's syndrome. It appears that the addition of EBV to the apparently normal lymphocytes of an AT patient revealed either a quiescent clone or an increased chromosome fragility. (17 refs)

79-2295 Correlation of a Specific Chromosomal Marker, 21q-, and Retroviral Indicators in Patients with Thrombocythemia. (Eng) Fuscaldo, K. E. (Dept. Medical Oncology and Hematology, Herbert L. Orlovitz Inst. Cancer and Blood Diseases, Hahnemann Medical Coll. and Hosp., Philadelphia, PA); Erlick, B. J.; Fuscaldo, A. A.; Brodsky, I.; Zaccaria, A. *Cancer Lett* 6(1): 51-56; 1979.

Thirty-eight patients with myeloproliferative disorders (MPD), including polycythemia vera, essential thrombocythemia, chronic myelocytic leukemia, and acute nonlymphocytic leukemia, were evaluated in Philadelphia (30 patients) and in Bologna, Italy (8 patients), for the presence of chromosomal markers. Twenty-eight patients were positive for the chromosomal anomaly 21q- and eight were negative. The 30 Philadelphia patients were evaluated for the presence of RNA-directed DNA-polymerase (RDDP) which is indica-

tive of retroviral activity. Sixteen patients were positive for RDDP and five were negative. There was a positive correlation between the presence of viral and chromosomal markers. Viral indicators were not found in platelet material when the 21q- deletion in dividing bone marrow cells was absent. The identification of a specific chromosomal marker, 21q-, may be important in understanding the etiology of these MPD. The fact that viral particles were detected only in cells with a deletion of the long arm of chromosome 21 may indicate an enhanced expression of virus in those cells in which the antiviral effects of chromosome 21 were impaired. 79-2296 Myelofibrosis and Acute Lymphoblastic Leukemia in a Child with Down Syndrome. (Eng) Nordan, U. Z. (Div. Hematology, Dept. Pediatrics, State Univ. New York at Buffalo, Buffalo, NY); Humbert, J. R. *J Pediatr* 94(2): 253-255; 1979.

The case of an 8-yr-old girl with Down's syndrome who developed myelofibrosis with concurrent acute lymphoblastic leukemia is presented. Bone marrow aspiration showed scanty marrow tissue with 21% lymphoblasts and 9.5% monocytes. Bone marrow biopsy showed hypoplasia and myelofibrosis with increase marrow reticulin. Acute leukemia and myelofibrosis may reflect extreme examples of the disruption of bone marrow proliferation control mechanisms in Down's syndrome. (9 refs)

79-2297 Hairy Cell Leukemia-associated Familial Lymphoproliferative Disorder. Immunologic Abnormalities in Unaffected Family Members. (Eng) Cohen, H. J. (Medical Service, Veterans Adm. Hosp., 508 Fulton St., Durham, NC, 27705); Shimm, D.; Paris, S. A.; Buckley, C. E.; Kremer, W. B. *Ann Intern Med* 90(2): 174-179; 1979.

A family in which members of three generations were affected by hematologic malignancies was studied. The proband had hairy cell leukemia, a brother had chronic lymphocytic leukemia, the father had chronic myelogenous leukemia, and a nephew had a cutaneous and CNS lymphoma. The proband and his brother were HLA identical to a normal sister; the third affected family member with lymphoma shared no HLA antigens. There was no clinical evidence for immune deficiency in 17 unaffected family members, but several showed an abnormally low percentage of cells forming sheep RBC rosettes, suggesting a decrease in T-cell number and expansion of a null cell pool. Several family members also

showed an abnormally low response to phytohemagglutinin and concanavalin A as well as a markedly reduced cutaneous hypersensitivity reaction. When tested for complement-fixation viral antibody titers to commonly encountered viral antigens, family values were considerably below normal values for all antibodies except those to Cocksackie B4. The decreased immune function in these family members suggests a role for the immune system in the emergence of hairy cell leukemia and other lymphoid malignancies. (26 refs)

- 79-2298 Lymphoproliferative Disease in Two Sisters.** (Eng) Garrett, J. V. (Christie Hosp., Withington, Manchester M20 9BX, England); Newton, R. K. *Br Med J* 1(6158): 234-235; 1979.

The occurrence of chronic lymphatic leukemia (CLL)-type lymphocytosis in two sisters is reported. One sister, aged 82, had ordinary-type CLL. One of her three children had died of pancreatic carcinoma. The second sister, aged 75, had prolymphocytic leukemia. Of her four children, one had died of Still's disease and one of ovarian carcinoma. One of the sisters' six siblings had colon carcinoma; the others had unremarkable histories. The simultaneous occurrence of two forms of lymphoproliferative disease in two sisters seems likely to be associated with some inherited instability of the lymphocyte system. (4 refs)

- 79-2299 Congenital Agranulocytosis Terminating in Acute Myelomonocytic Leukemia.** (Eng) Rosen, R. B. (Dept. Pediatrics, City of Hope Medical Center, 1500 E. Duarte Rd., Duarte, CA, 91010); Kang, S. J. *J Pediatr* 94(3): 406-408; 1979.

The development of acute nonlymphocytic leukemia in a 14-yr-old boy with an infantile genetic agranulocytosis (IGA)-like disease is reported. The IGA-like disease was characterized by onset in infancy, recurrent infections, agranulocytosis, monocytosis, and deficiency of marrow neutrophil granulocytes beyond the myelocyte stage. A 9-yr-old sister had Down's syndrome. Over the years, the patient had received numerous antibiotics, including the possible leukemogen chloramphenicol. Cytogenetic studies were normal at the time of diagnosis of the leukemia. Although the possibility that the leukemia was a chance occurrence cannot be excluded, this case supports the classification of congenital agranulocytosis as a preleukemic state or a condition with a predilection to terminate in leukemia. (10 refs)

- 79-2300 Heterotransplantation of a Human Leukemic T-Cell Line in Hamsters.** (Jpn) Hiraki, S. (Dept. Second Internal Medicine, Okayama Univ. Medical Sch., Okayama, Japan); Miyoshi, I.; Nakamura, K.; Ohta, T.; Ikeda, H.; Tsubota, T.; Uno, J.; Tanaka, T.; Kimura, I. *Jpn*

J Clin Hematol 19(11): 1519-1522; 1978.

A leukemic T-cell line (TALL-1) from the bone marrow of a 28-yr-old man in the terminal stage of T-cell lymphosarcoma was recently established in permanent culture. The ip implantation of $1.8-2.9 \times 10^7$ TALL-1 cells in seven newborn Syrian hamsters treated with rabbit anti-hamster thymocyte serum gave rise to invasive tumors after 26-41 days. There was involvement of the parathymic lymph nodes, liver, gallbladder, brain, meninges, and uvea. The donor had widespread leukemic involvement, including the meninges and eyes, during his clinical course. This in vivo model system may be useful for studies of the characteristics of human T-cell leukemia-lymphoma. (10 refs)

- 79-2301 Membrane Markers in Human Lymphoid Malignancies: Clinicopathological Correlations and Insight into the Differentiation of Normal and Neoplastic Cells.** (Eng) Seligmann, M. (Lab. Immunochemistry and Immunopathology, Res. Inst. Blood Diseases, Hopital Saint-Louis, 75475 Paris Cedex 10, France); Preud'homme, J. L.; Brouet, J. C. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 859-876; 1978.

Immunologic and enzymatic markers in human lymphoid malignancies that are relevant to the clinicopathological pattern or to the differentiation of normal lymphoid cells were studied. In 167 untreated patients with acute lymphoblastic leukemias (ALL), B and T cells were present, respectively, in 10% and 25% of the patients; non-B, non-T cells were found in 65% of the patients. In 85% of the cases of T-derived ALL, most blast cells exhibited a strong acid phosphatase positivity with numerous granules in the Golgi area, but such positivity was found in < 10% of the non-T, non-B ALL cases. The following features were more often present in T-derived ALL than in non-B, non-T ALL: a tumoral presentation, a mediastinal mass, and high blast-cell blood counts. The incidence of continuous complete remission was higher in the non-T, non-B subgroup compared to the T subgroup. T-derived ALL had slightly lower mean terminal deoxynucleotidyl transferase activity, compared with the non-T, non-B group. Nineteen of 23 chronic lymphocytic leukemia (CLL) cases exhibited clinical and hematological features indicative of a T origin of the leukemia. The differentiation patterns of B-cell proliferations in the CLL cases are discussed. It is suggested that the proliferating cells may not necessarily represent the target cells for the neoplastic event and that, even when they appear to be frozen at a given stage of differentiation, the tumor cells may arise from a precursor cell. (73 refs)

- 79-2302 Genetic Control of Hemoglobin Production by Murine Erythroleukemic Cells.** (Eng) Skoultchi, A. I. (Dept. Cell Biology, Albert Einstein Coll. Medicine, Bronx, NY, 10461); Benoff, S.; Bruce, S. A.; Lin, P. F.; Lonial, H.; Pyati, J. *Cold Spring Harbor Conf Cell Proliferation*

Vol. 5(Book B), 994 pp.; 723-740; 1978.

Genetic control of Hb synthesis was studied in Friend murine erythroleukemic (EL) cells by cell hybridization and by the isolation and characterization of noninducible EL cells. A hypoxanthine-guanine phosphoribosyltransferase (HGPRT)-deficient EL cell line lacking a normal X chromosome was fused with mouse bone marrow cells and mouse lymphoma cells. Hb inducibility was demonstrated in hybrid lines in which most cells did not bear an X chromosome, whereas the lines that had retained an X chromosome were inhibited for Hb production. Karyological analysis failed to reveal a correlation between inhibition of inducibility and any chromosome other than the X chromosome. This finding was confirmed by measurements of HGPRT activity in cell extracts: hybrid lines having many cells with a normal X chromosome had high levels of HGPRT activity, but lines with few cells bearing an X chromosome had low levels. Hybrid cells bearing an X chromosome donated by bone marrow cells accumulated large amounts of polyribosomal globin messenger RNA (mRNA), suggesting that the effects of the X chromosome lie at the level of heme biosynthesis. Growth of the X-chromosome-bearing hybrid cells in dimethyl sulfoxide (DMSO)-containing medium supplemented with 10^{-4} M hemin or 10^{-3} M δ -aminolevulinic acid (ALA) gave results that indicate that the X-linked locus of bone marrow cells inhibits heme biosynthesis at the step catalyzed by ALA synthetase. In five noninducible variants examined, heme accumulation was not detected and DMSO did not stimulate an increase in the number of transferrin receptors. Three of these variants had increased chromosome numbers compared with the parental cell line, which might indicate that the altered phenotype of these cell lines is due to a change in the amount and/or arrangement of the genetic material. (34 refs)

79-2303 A Case of Chronic Myelogenous Leukemia Associated with Gastric Cancer. (Jpn) Fujii, H. (Third Dept. Internal Medicine, Kyoto First Red Cross Hosp., Kyoto, Japan). *Jpn J Clin Hematol* 19(12): 1677-1683; 1978.

The occurrence of chronic myelogenous leukemia (CML) associated with gastric cancer in a 46-yr-old Japanese woman is reported. She was admitted with complaints of hematemesis and melena. An ulcerated lesion of the gastric antrum was found through an upper gastrointestinal series and endoscopy; biopsy indicated the presence of a Group V lesion. Peripheral blood tests revealed anemia, leukocytosis with immature granulocytes, and normal neutrophil alkaline phosphatase activity. The vitamin B12 level was high. The bone marrow was markedly hypercellular, and chromosome analyses of these cells showed that the patient was positive for the Philadelphia chromosome and that she had a 46,XX, t(9;22) (q⁺;q⁺) karyotype. A diagnosis of CML associated with gastric cancer was made. The resected gastrectomy specimen contained a 2-x 2-cm Borrmann Type II gastric cancer that, upon histologic examination, was shown to be

a tubular mucinous micronodular adenocarcinoma. From 1944 to 1975, the incidence of reported cases of leukemia and coexistent primary cancer in Japan was 0.56%-0.64%. Five of the total 532 cases were CML associated with gastric cancer. (23 refs)

79-2304 Five Cases of Malignant Lymphoma Associated with Early Gastric Cancer. (Eng) Takenaka, T. (Dept. Internal Medicine and Surgery, National Cancer Center Hosp., 5-1-1, Tsukiji, Chuo-ku, Tokyo 104, Japan); Sakano, T.; Kitahara, T.; Kitaoka, H.; Watanabe, S.; Hirota, T. *Jpn J Clin Oncol* 8(2): 209-217; 1978.

The occurrence of malignant lymphoma (ML) associated with early gastric cancer in five patients (2 women aged 40 and 73 yr, 3 men aged 62, 66, and 75 yr) is reported. There were two cases of diffuse large lymphoid-type ML and three cases of Hodgkin's disease. The ML was antecedent or coincidental in four patients. The early gastric cancer was a well-differentiated adenocarcinoma in three patients and a mucinous adenocarcinoma in two. Laboratory studies revealed decreases in WBC and RBC in all five patients and decreased lymphocytes in four patients between the onsets of the different malignancies. IgM was decreased in four patients and the skin response to purified protein derivative of tuberculin was negative in 3/4 patients tested. In all five cases, complaints relating to the second neoplasms were considered at first to be related to the known primary tumors. It was not clear whether the primary neoplastic disease rendered the patient more prone to development of the second tumor or whether the cancer therapy in certain settings decreased the immune response, leading to a second neoplastic change. Malignant tumors were found in relatives of three patients. It is necessary to investigate the relationship between aging and cellular immunity in patients with ML. (18 refs)

79-2305 Sarcomas in a Child and Her Father. (Eng) Parry, D. M. (Clinical Epidemiology Branch, NCI, A521 Landow Bldg, Bethesda, MD, 20014); Mulvihill, J. J.; Miller, R. W.; Spiegel, R. J. *Am J Dis Child* 133(2): 130-132; 1979.

The occurrence of sarcomas in a 4.5-yr-old girl and her 30-yr-old father is reported. The girl had an embryonal rhabdomyosarcoma of the right foot and popliteal space, poor hearing (possibly related to recurrent ear infections), and at least four cafe au lait spots (CALs) on her trunk. CALs were not reported on any other family member. The father had an osteosarcoma at an atypical site for this tumor, the mid-humerus. He had been employed for 8 yr in a zinc smelter and had a lifelong history of residence in an area of industrial pollution. The area also had excessively high death rates in white men from bone and connective tissue cancer. The only other case of cancer in the family was an unspecified malig-

nant neoplasm in a maternal first cousin of the father. The differential etiologic diagnoses were: osteosarcoma, possibly related to occupational exposures, in the father; sporadic multiple neurofibromatosis (NF) in the daughter; hereditary NF; and familial sarcoma-carcinoma syndrome. These diagnoses are discussed and recommendations are made for family studies to determine the appropriate diagnosis. (12 refs)

- 79-2306 Angioimmunoblastic Lymphadenopathy and Immunoblastic Sarcoma. Ultrastructural Study of a Case.** (Spa) Forteza Vila, J. (Servicio Anatomia Patologica, Ciudad Sanitaria 'Juan Canalejo', La Coruna, Spain); Rodriguez Fernandez, J. M.; Villamayor Alvarez, M.; Guitian Barreiro, D. *Sangre (Barc)* 24(1): 59-72; 1979.

Chronic lymphoid leukemia was diagnosed in a 47-yr-old man hospitalized with marked asthenia and anorexia. Bone marrow and lymph node biopsies performed immediately after admission revealed angioimmunoblastic lymphadenopathy (AIL). Bone marrow, lymph node, and liver biopsies performed 6 mo later demonstrated infiltrations of immunoblastic sarcoma (IS). Histological and ultrastructural examination of the first lymph node biopsy specimen showed partial destruction of the lymph node structure with diffuse infiltration by pleomorphic lymphocytes (predominantly immunoblasts) and vascular proliferation. Examination of the second specimen showed disappearance of the vascular proliferation, total obliteration of the lymph node structure by pleomorphic lymphocytes (predominantly immunoblasts), and numerous isolated epithelioid cells. Bone marrow biopsy 6 mo later showed lymphocyte infiltration with an immunoblast predominance and destruction of the normal architecture. The marked selective erythroblastopenia and the absence of diffuse bone marrow infiltration may be explained by the existence of antierythroblast antibodies. (25 refs)

- 79-2307 Inappropriate Antidiuretic Hormone Complicating Histiocytic Lymphoma.** (Eng) Kelton, J. G. (Room 4N48, Dept. Pathology, McMaster Univ. Medical Centre, 2100 Main St. W., Hamilton, Ontario, Canada L8S 4J9); Logue, G. *Arch Intern Med* 139(3): 307-308; 1979.

The case reports of two patients with histiocytic lymphomas complicated by hyponatremia resulting from the inappropriate antidiuretic hormone (IADH) syndrome are presented. In both patients, hyponatremia appeared simultaneously with hypertonicity of the urine in the absence of signs of hypovolemia or abnormal renal or adrenal function. Hyponatremia occurred when there was max tumor bulk and not following tumor regression with therapy. (19 refs)

- 79-2308 Kaposi's Sarcoma: A Brief Review of a Rare Disease.** (Ger) Obrist, R. (Department fur In-

nere Medizin, Abteilung fur Onkologie, Kantonsspital, CH-4056 Basel, Switzerland); Hartmann, D.; Obrecht, J. P. *Onkologie* 1(1): 20-22; 1978.

A case of Kaposi's sarcoma (KS) in a 50-yr-old Bantu from Tanzania is described briefly, and the relevant literature is reviewed. Malignant degeneration of epithelial cells is most often suggested as the cytogenetic basis of KS, although reticuloendothelial and Schwann cells and pericytes have also been implicated. The frequency of KS increases linearly with age, unlike carcinomas that increase exponentially. The incidence in men is 10 times that in women. A virus etiology is suggested by the high incidence of KS in the malaria belt (Central and East Africa). The incidence of increased cytomegalovirus antibody titers is significantly higher in KS patients. Of interest is the fact that with progression of KS these titers become lower and less frequent. Disturbances of the immune system are suggested by the frequency of second tumors in KS patients. In a group of 63 patients, 18 died of a second tumor; 8/18 had malignant lymphoma. Second tumors are more common among Europeans and Americans than among African blacks; more cytostatic treatment may be the cause of this difference. (16 refs)

- 79-2309 Anaplastic Carcinoma of the Thyroid Gland. An Ultrastructural Study on Four Cases.** (Eng) Hayashi, Y. (Dept. Pathology, Hiroshima Univ. Sch. Medicine, 1-2-3 Kasumi, Hiroshima, Japan); Tokuoka, S. *Acta Pathol Jpn* 29(1): 119-133; 1979.

The ultrastructural features of four cases of anaplastic carcinoma of the thyroid, one small cell carcinoma and three giant cell carcinomas, are presented. In the small cell carcinoma, fine cytoplasmic interdigitations and junctional complexes between apposing cytoplasmic membranes of neighboring tumor cells and a few microlumina within tumor cell clusters surrounded by well-defined basal lamina were seen. In the giant cell carcinomas, occasional cytoplasmic interdigitations as well as desmosomal structures were detected even in tumor cells that were markedly pleomorphic and anaplastic. Abundant cytoplasmic organelles, including well-developed Golgi apparatus, rough endoplasmic reticulum, and a few mitochondria, were seen in the tumor cell cytoplasm of all four carcinomas. All the giant cell carcinomas showed evidence of a fairly well-differentiated tumor within the anaplastic carcinoma, indicating the probable preexistence of a more differentiated benign or malignant epithelial neoplasm that subsequently underwent anaplastic transformation. The findings support the hypothesis that these anaplastic tumors are derived from the follicular epithelium of the thyroid gland. In addition, the small cell carcinoma cells provide evidence suggesting that the functional differentiation of carcinoma cells occurs to a certain extent, but not to the extent that they are able to produce thyroglobulin. (20 refs)

- 79-2310 Seeding of Parotid Carcinoma along Vim-Silverman Needle Tract.** (Eng) Yamaguchi, K. T. (Dept. Otolaryngology, Veterans Admin. Hosp., 150 S. Huntington Ave., Boston, MA, 02130); Strong, M. S.; Shapshay, S. M.; Soto, E. *J Otolaryngol* 8(1): 49-52; 1979.

A case of parotid tumor seeding to the skin, secondary to Vim-Silverman (V-S) needle biopsy, occurred in an 82-yr-old man. During an 11-mo follow-up period after the biopsy, a slowly enlarging mass involving the skin at the biopsy site was detected. The entire tumor mass was excised. The patient died approximately 3 mo postoperatively; an autopsy could not be obtained. Histological sectioning of the surgical specimen revealed carcinoma growing in a tractlike configuration extending from the sc tumor mass to the ulcerated skin surface. The tumor was diagnosed as a poorly differentiated mucoepidermoid carcinoma of the parotid gland. This case demonstrates the possible but rare complication of V-S needle biopsy. (9 refs)

- 79-2311 Development of a Neonatal and Metastatic Murine Neuroblastoma Model.** (Eng) Sheffler, B. A. (Dept. Biological Chemistry, Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA, 17033); Repman, M. A.; Schengrund, C. L. *Cancer Res* 39(3): 711-713; 1979.

A neonatal murine neuroblastoma (NB) model and a murine NB model for metastatic involvement were developed with the use of syngeneic A/Jax mice [neonates (24- to 48-hr-old mice), pups (10-day-old mice), and adults (6- to 8-wk old mice)]. The S20Y NB cell line used was cloned from the A/Jax murine C1300 NB. Dose-response studies of adult male and female mice given sc injections showed no meaningful sex-related differences in either the appearance or the growth rate of the tumors. No significant difference in tumor appearance or growth rate was observed between pups and adults. However, neonates inoculated with the same number of cells as the adults demonstrated a marked delay in tumor appearance. Neonates challenged with 5×10^5 cells showed a 75% reduction in tumor appearance compared with their adult counterparts. An inoculum of 2×10^5 S20Y cells resulted in 100% of the adult mice developing tumors within 26 days, but none of the neonates had developed tumors > 90 days postinjection. Comparison of the sc and intradermal routes of injection of NB cells was made using adult male mice. Tumors developed at approx the same rate. The intradermal tumors were removed at various stages of growth. Over 90% of the mice that underwent surgery and a similar percentage of the mice with intradermal tumors that did not have surgery subsequently developed metastases to the lymph nodes, liver, lungs, adrenals, heart, kidney, spleen, and abdominal area, sites that commonly harbor metastatic lesions in human NB. Metastases at these sites were not observed with sc inoculations. (13 refs)

- 79-2312 Development of a Metastatic Brain Tumor Model in Mice.** (Eng) Conley, F. K. (Div. Neurosurgery, Dept. Surgery, Stanford Univ. Sch. Medicine, Stanford, CA, 94305). *Cancer Res* 39(3): 1001-1007; 1979.

This study reports an easily accomplished and reliable model of metastatic tumor in the brains of female C3H/Bi mice. Five experimental groups of mice received left intracardiac injections of a syngeneic KHT sarcoma cell suspension (1×10^5 cells) and were followed until death. Two groups of mice also received 3,000 rads of radiation to a limited cardiac port 24 hr after tumor injections. All mice were completely autopsied, and the brains were examined both grossly and microscopically. Metastatic brain tumors developed in 60% to 70% of the mice; the tumor foci were parenchymal, usually multifocal, and they had wide distribution throughout the cerebrum, brainstem, and cerebellum. There was an occasional meningeal tumor, but tumors never involved the skull, choroid plexus, pituitary gland, or local extracranial structures. Cardiac irradiation did not increase the number or the mean survival of mice with metastatic brain tumors, but it did decrease the total tumor burden of individual animals by markedly reducing the incidence of metastatic lung tumors and totally preventing tumor infiltration of the heart. This demonstration of consistently produced blood-borne metastatic brain tumors in mice should provide a valuable research model that will allow the CNS to be studied for internal mechanisms and/or external factors that influence that arrest and growth of embolic tumor cells in the brain. (44 refs)

- 79-2313 Angiographic Demonstration of Infratentorial Tumors with Concordant Manifestation, Localization, and Histology in Monozygotic Twins.** (Ger) Voigt, K. (Medizinisches Strahleninstitut, Abteilung für Neuroradiologie, Röntgenweg 11, 7400 Tübingen, W. Germany); Marquardt, B. *ROEFO* 130(1): 89-94; 1979.

The occurrence of craniospinal subependymomas with identical manifestations, localization, and histology in a pair of monozygotic twins is reported. Literature cases of histologically confirmed concordant brain tumors in seven sets of twins and three other cases suspected to be concordant are reviewed. The twins reported here were healthy until age 22. The localization of the tumors was established by computer tomography (CT), angiography, ventriculography, and surgery, and it was found to be nearly identical. The tumors had grown through the foramen magnum, and they extended from the fourth ventricle to the second cervical vertebra. The tumors showed no signs of malignancy, and there have been no indications of regrowth during the 3 postoperative yr. A CT scan was used for follow-up. Genetic factors or a hereditary disposition may play a role in the development of cerebral tumors in twins. (24 refs)

- 79-2314 Retinoblastoma with 13q--Chromosomal Deletion Associated with Maternal Paracentric Inversion of 13q.** (Eng) Sparkes, R. S. (Div. Medical Genetics, Dept. Medicine, Center Health Sciences, Univ. California, Los Angeles, CA, 90024); Muller, H.; Klisak, I.; Abram, J. A. *Science* 203(4384): 1027-1029; 1979.

Cytogenetic studies in a girl with sporadic unilateral retinoblastoma and mental retardation demonstrated an interstitial deletion in the long arm of chromosome 13. Her mother was found to have a paracentric inversion of one chromosome 13; the deleted chromosome in the daughter was derived from the mother's normal chromosome 13. (5 refs)

- 79-2315 Complete Heart Block Caused by Metastatic Tumor of the Heart. Report of One Case.** (Fre) Almange, C. (Service de Cardiologie B, Centre Hospitalier Universitaire, 2 rue de l'Hotel-Dieu, 35011 Rennes Cedex, France); Lebreteux, T.; Louvet, M.; Courgeon, P.; Guerin, D.; Leborgne, P. *Sem Hop Paris* 50(45/46): 1419-1424; 1978.

An epidermoid carcinoma of the esophagus metastasized to the heart of a 59-yr-old man. The metastases were located in the interventricular septum and caused complete atrioventricular block. Histological examination showed destruction of the conduction fibers. The patient lived 10 mo after diagnosis, an unusually long survival for atrioventricular metastatic block. (32 refs)

- 79-2316 Metastatic Tumors in the Temporal Bone--A Pathophysiologic Study.** (Eng) Jahn, A. F. (Banting Inst., 100 College St., Room 81, Toronto, Canada); Farkashidy, J.; Berman, J. M. *J Otolaryngol* 8(1): 85-95; 1979.

Pathophysiologic studies were made of 19 temporal bones (TPB) from 11 patients (7 men and 4 women aged 18-90 yr) who had metastatic TPB disease from a distant primary tumor. Clinical features included a high incidence of occult TPB involvement (7/10 clinically documented cases), a considerable incidence of melanoma (3/10 cases), and a variable correlation between clinical findings and pathologic localization of the tumor in the TPB. Two distinct modes of tumor spread within the TPB were observed on pathologic examination: vascular-osseous (petrous apex, mastoid, middle ear, and external canal) and perineural (nerves in the internal canal branches and labyrinthine end-organs). Every case was involved by one or both of these routes, and no case of cerebrospinal fluid-borne metastasis to the perilymphatic space was seen. The earliest metastatic focus appeared to gain a foothold in the marrow-containing portion of the petrous bone. Perineural tumor spread was distinct from and unrelated to the progress of bony tumor involvement. The initial point of entry into the nerve trunk was evidently associated with intraneural vessels, although in some cases the relationship was not readily demonstrated. The external canal was

involved extensively in spite of an intact tympanic membrane. Considering that the initial focus of tumor often lies within the petrous bone, hidden by apparently uninvolved dura and petrous ridge, it may well escape detection at routine autopsy. TPB metastasis may be the initial sign of cancer or the first evidence of skull base invasion. Occult metastases may be discovered through TPB tomography. (10 refs)

- 79-2317 Nasopharyngeal Carcinoma in Siblings.** (Eng) Fischer, R. A. (Yale-New Haven Hosp., New Haven, CT); Wharam, M. D.; Kashima, H. K. *Ear Nose Throat J* 58(2): 93-97; 1979.

The third documented occurrence of a familial aggregation of nasopharyngeal carcinoma (NPC) in the US is presented, and the literature on all familial aggregations of this tumor is reviewed. NPC was diagnosed in a 13-yr-old boy whose initial symptoms were swelling of the right parotid area and several spontaneous nosebleeds. Seven years later, NPC was diagnosed in his 17-yr-old sister, whose initial symptom was a high right neck mass that gradually grew and became tender. Thirty-three familial clusters among Chinese families have been reported, with horizontal associations (sibling-sibling) being more common than vertical associations (parent-child). In a retrospective survey in Hong Kong, the risk of NPC among close family members of NPC patients (3%) was found to be 10-fold greater than that for family members of patients with other types of cancer. Among non-Orientals, 10 familial clusters of NPC have been reported. The male:female ratio among these patients is 2:1. Sixty-five percent of the patients were <30 yr old at the time of onset, and they had a younger age distribution than NPC patients in general. The ages at onset for affected sibs were similar, and the av difference in date of onset within families was <4 yr. The occurrence of this disease in families clustered closely in time is consistent with a hypotheses of a common environmental causative agent and/or a genetic predisposition. (18 refs)

- 79-2318 Changes in Bronchial Epithelium in Relation to Cigarette Smoking, 1955-1960 vs. 1970-1977.** (Eng) Auerbach, O. (151B, Veterans Admin. Medical Center, E. Orange, NJ, 07019); Hammond, E. C.; Garfinkel, L. *N Engl J Med* 300(8): 381-386; 1979.

To determine whether the drop in tar and nicotine levels in cigarette smoke that began in the 1950's has been reflected in less extensive histologic changes in the bronchial epithelium of cigarette smokers, 20,424 bronchial tube sections taken at autopsy from men not dying of lung cancer were examined. The sections were taken from 211 men who died between 1955 and 1960 (Group 1) and 234 men who died between 1970 and 1977 (Group 2). Regular smokers numbered 154 in Group 1 and 181 in Group 2. Changes studied included basal-cell hyperplasia, loss of cilia, and occurrence of cells

with atypical nuclei. In both groups, these changes occurred much less frequently in nonsmokers than in cigarette smokers, and they increased in frequency with the amount of smoking, adjusted for age. Sections with advanced histologic changes in Group 1 subjects occurred in 0% of nonsmokers, in 2.6% of those smoking 1-19 cigarettes daily, in 13.2% of those smoking 20-39 cigarettes daily, and in 22.5% of those smoking > 40 cigarettes daily. In Group 2, the percentages were 0%, 0.1%, 0.8%, and 2.2%, respectively. These results are consistent with evidence from epidemiologic studies indicating that death rates from lung cancer are lower among men who smoke low-tar/nicotine cigarettes than among men who smoke the same number of high-tar/nicotine cigarettes per day and with the fact that there has been a great decrease in the tar/nicotine content of cigarette smoke over the last 25 yr. (12 refs)

79-2319 Thrombocytosis and Primary Bronchial Carcinoma. Study of 164 Patients with Bronchial Carcinoma. (Fre) Bouvenot, G. (Service de Medecine Interne, Hotel-Dieu, 6 place Davel, 13224 Marseille Cedex 1, France); Bartolin, R.; Dugue, P.; Heim, M.; Delboy, C.; Charpin, J. *Sem Hop Paris* 55(1/2): 26-29; 1979.

In a series of 164 patients with primary bronchial carcinoma (114 malpighian epidermoid, 17 anaplastic small cell, and 33 adenocarcinoma), 60 had thrombocytosis (platelet count > 400,000/mm³). No statistical relationship was observed between elevated platelet count and the histological type of tumor, presence of the inflammatory syndrome (serum α -globulin > 11%, blood fibrin > 4.4 g/liter, sedimentation rate > 40), or presence of metastases. A significant correlation was observed between thrombocytosis and anemia (Hb < 12 g/100 ml). Respiratory function studies did not show any correlation with thrombocytosis. A platelet count when correlated with x-ray studies may be of value in the diagnosis of lung cancer. (13 refs)

79-2320 Lung Cancer and Pneumothorax (2 Letters to Editor). (Eng) Snell, N. J. (Central Chest Clinic, Reading, Berkshire, England); Hyde, L.; Hyde, C. I. *JAMA* 241(11): 1107; 1979.

In contrast to previous statements, undiagnosed lung cancer may be present in patients with pneumothorax (PT) who are < 40 yr of age. PT occurs more commonly with secondary malignant lung disease, particularly metastases from bone sarcomas, and this is nearly always seen in those younger than 40 yr. At least 68 cases of PT with primary lung cancer and 86 cases with metastatic disease have been reported. However, a previously recorded case and the comments on it was intended to refer only to patients with simultaneous primary lung cancer and spontaneous PT. (5 refs)

79-2321 Malignant Transformation of Cicatricial Stenosis (due to a Caustic Agent) of the Esophagus. (Fre) Gaillard, J. (Service O.R.L., Hopital de la Croix-Rousse, 93 Grande-Rue-de-la-Croix-Rousse, 69004 Lyon, France); Haguenaer, J. P.; Romanet, P. *Ann Otolaryngol Chir Cervicofac* 95(6): 395-399; 1978.

Four patients in whom esophageal carcinoma developed at healed chemical burn sites are described. The carcinomas were observed between 29 and 57 yr following the initial injury. Trauma due to artificial dilatation of the stenosed esophagus may also be involved in the development of the carcinoma. (no refs)

79-2322 Distant Metastases to Bone from Bladder Carcinoma: Report of Three Cases. (Eng) Dunnick, N. R. (Dept. Diagnostic Radiology, NIH, Clinical Center, Building 10, Room 6S211, Bethesda, MD, 20014); Anderson, T. *Am J Roentgenol* 132(3): 469-470; 1979.

The cases of three patients with distant bone metastases from transitional cell carcinoma of the bladder are presented. The sites of metastases in the first two patients, the right talus and the right mandible, respectively, are rare; deep vein thrombosis and dental abscess were initially suspected in each case. In the third patient, metastases occurred in the right pedicle of T6 and in the parietal region of the skull. (6 refs)

79-2323 Primary Malignant Tumor of the Liver Associated with the Ingestion of Oral Contraceptives. (Fre) Leclerc, J. (Clinique Medicale et Endocrinologique, CHU de Nancy, Hopital de Brabois, F 54500 Vandoeuvre-Nancy, France); Meot, B.; Marchal, F.; Mizrahi, R.; Collard, F.; Begue, J. Y.; Rauber, G.; Hartemann, P. *Nouv Presse Med* 8(5): 346-349; 1979.

A case of primary liver carcinoma occurring in a 42-yr-old woman who had been taking oral contraceptives for 10 yr is presented. The diagnosis was made by biopsy. Twenty-one similar cases have been reported in the literature. There are also approx 200 literature cases of benign liver tumor in patients that had been taking oral contraceptives, but the etiological role of oral contraceptives in either benign or malignant tumors has not been established. The regression of certain benign tumors when the steroids are discontinued is the essential argument in favor of this association. In some patients, the association of benign lesions with hepatic carcinoma suggests a single pathogenesis. (23 refs)

79-2324 Hepatocellular Carcinoma in Siblings. (Ger) Sitzmann, F. C. (Universitäts-Kinderkliniken Erlangen, 6650 Homburg/Saar, W. Germany); Lindinger, A. *Therapiewoche* 29(8): 1287-1291; 1979.

The cases of a brother and sister who died in childhood of hepatocellular carcinoma (HCC) are reported, along with the incidence of liver disease in their family. The boy had icterus at 2 wk and at 3 mo of age. He was exposed at 4 mo to an aunt who, 4-5 mo previously, had hepatitis, and at 7 mo he developed marked icterus. A biopsy at 10 mo showed periportal fibrosis of the liver. Cortisone was given several times. The liver rapidly increased in size starting at age 6.5, and HCC was diagnosed soon thereafter. The boy died at age 7. An extensive, multicentric liver carcinoma that had invaded the portal vein but showed no signs of metastasis was found at autopsy. The sister was first examined for an enlarged abdomen at 1.5 yr of age; liver cirrhosis was found at laparoscopy. The disease began to progress rapidly, with sizable enlargement of the liver, when she was 5.75 yr old. At autopsy finely granular cirrhosis, a multicentric HCC that had extended into the portal vein and both of its branches, and lung metastases were found. The disease courses of the siblings seemed very similar. Their paternal grandfather had γ -chain plasmacytoma. Both maternal grandparents had liver cirrhosis that developed between age 30-40. The maternal grandfather, in whom the disease was not progressing, was positive for anti-hepatitis B surface antigen (HBsAg) and anti-HB core antigen and negative for HBsAg. The children's mother had chronic aggressive hepatitis at age 28 and was positive for HBsAg. A 9-yr-old sibling, who was examined carefully, appears to be healthy. (38 refs)

- 79-2325 **Electrophoretic Variant of Fetal Intestinal Alkaline Phosphatase in a Patient with Cirrhotic Liver.** (Eng) Kudo, S. (Third Dept. Internal Medicine, Osaka Univ. Sch. Medicine, Fukushima 1-1-50, Fukushima-ku, Osaka 553, Japan); Higashino, K.; Yamamura, Y. *Gann* 70(1): 15-19; 1979.

Two enzymes observed in the hepatic tissue of a patient with posthepatic cirrhosis were studied. On thin-layer polyacrylamide gel electrophoresis, the alkaline phosphatase (AP) isoenzyme of a liver extract from this patient showed a broad band with high activity and two additional bands with lower activity at the anodal side. These two anodal bands and the Kasahara isoenzyme (a fetal intestinal AP found in the sera of hepatoma patients) were slightly inhibited by L-homoarginine and almost completely inhibited by L-phenylalanine. Like the fetal intestinal AP, the anodal bands were moderately stable to heat treatment and were not inactivated by treatment with neuraminidase (1 mg/ml) or sodium dodecyl sulfate (10 g/liter). The two enzymes cross-reacted with anti-adult intestinal AP antibody, but not with antibody specific for placental AP. The enzymes therefore seem to be variants of a fetal intestinal AP. Their occurrence in cirrhotic liver along with their reported occurrence in hepatoma support the concept that cirrhosis of the liver is a precancerous state. (13 refs)

- 79-2326 **Paraneoplastic Syndromes of the Kidney.** (Fre) Jimenez Cruz, J. F. (Service d'Urologie, Cite Sanitaire de la Securite sociale, Barcelona, Spain); Rioja Sanz, C.; Garcia-Lopez, F.; Sole-Balcells, F. *Sem Hop Paris* 55(1/2): 74-79; 1979.

Paraneoplastic clinical signs observed in 10 patients (4 men, 6 women, aged 44-72 yr) with carcinoma of the kidney are reported. Hepatic dysfunction was the most common (41.5%) sign, followed by pain (38%), palpable mass (35%), and fever (18.8%). (31 refs)

- 79-2327 **Adenomatous Hyperplasia of the Gallbladder in Chronic Cholecystitis and Its Significance in Carcinogenesis.** (Pol) Piegza, S. (Oddz. Chirurgii Ogolnej, ZOZ dla Gornikow, ul. Sokolowskiego 4, 58-309 Walbrzych, Poland); Tyszkiewicz, S.; Turczynski, J.; Szklarz, Z. *Wiad Lek* 31(23): 1667-1670; 1978.

Adenomatous hyperplasia of the gallbladder was found in 94/227 patients who underwent surgery for chronic cholecystitis. Investigation of the surgical specimens revealed chronic glandular cholecystitis in 77.6% of the 94 patients (av age 44.9 yr), chronic adenomatous cholecystitis in 15.9% (av age 48.8 yr), and columnar cell adenocarcinoma in 6.3% (av age 45.5 yr). In agreement with data in the literature, these findings indicate that gradual adenomatous changes lead to gallbladder carcinoma. (12 refs)

- 79-2328 **Significance of Blood Vessel Invasion in the Involved Lymph Node as a Predictor of Blood-borne Metastases in Breast Cancer--Further Report.** (Eng) Izuo, M. (Dept. Surgery, Gunma Univ. Sch. Medicine, 3-39-15, Showa-machi, Maebashi-shi, Gunma 371, Japan); Akabani, O.; Okano, A.; Kawai, T. *Jpn J Clin Oncol* 8(2): 101-104; 1978.

Two hundred and fifty-six patients who had undergone radical mastectomy were investigated for blood vessel invasion in the primary tumor (BVIT), and 106 of these patients with regional lymph node metastasis were examined for blood vessel invasion within and in the vicinity of the involved lymph node (BVIN). BVIT was found in 69 (27.0%) patients. These patients, particularly those with regional node metastases (19.9% of the total population), showed a higher incidence of blood-borne distant metastases than those without BVIT. The incidence of blood-borne metastases was 6.1% in patients with neither BVIT nor BVIN, 12.5% in patients with BVIT but not BVIN, 40.9% in those with BVIN but not BVIT, and 48.6% in those with BVIT and BVIN. When the patients with positive BVIN were divided into three subgroups according to the grade of invasion, the incidence of blood-borne distant metastases was found to increase according to the grade of BVIN. The data suggest that blood vessel invasion, especially of the involved lymph nodes, is an important predictor of postoperative distant metastases. (9 refs)

79-2329 Malignant and Benign Papillary Lesions of the Breast. (Eng) Murad, T. M. (Div. Surgical Pathology and Cytology, Univ. Alabama Medical Center, University Station, Birmingham, AL, 35294); Swaid, S.; Pritchett, P. *Hum Pathol* 8(1): 379-390; 1977.

Criteria that may be helpful in classifying various proliferative changes of the breast and in separating papillary carcinoma from other benign papillary lesions are presented. Epithelial and papillary proliferations of the breast include papillomatosis, terminal duct hyperplasia, atypical duct hyperplasia, intraductal papilloma, and multiple papillomas. Papillary carcinoma of the breast tends to involve more than one duct system and is frequently seen after biopsy of a gross lesion rather than as an incidental microscopic finding. Papillary carcinoma tends to form one of four basic microscopic patterns, and frequently there is a mixture of two or more patterns within the same tumor. These patterns comprise the papilliform, reticular, cribriform, and microcystic types. The true incidence of benign proliferative changes in fibrocystic disease and the significance of these lesions in the later development of cancer were determined by studying 200 randomly selected cases of fibrocystic disease seen at least 10 yr earlier. Forty patients had intraductal papillomatosis or epithelial cell hyperplasia. The average age of these 40 patients was 44.5 yr (range 24-65). In 20 patients, the papillomatosis coexisted with the epithelial cell hyperplasia. None of the patients for whom complete follow-up data are available (up to 14 yr) developed cancer. Ultrastructural and histochemical studies suggest that both epithelial and myoepithelial cells participate in papillary breast lesions. (19 refs)

79-2330 Sexual Precocity and Thoracic Polyembryoma: Klinefelter Syndrome (Letter to Editor)? (Eng) Floret, D. (Clinique Medicale Infantile B, Hopital Edouard-Herriot, Place d'Arsonval, 69374 Lyon Cedex 2, France); Renaud, H.; Monnet, P. *J Pediatr* 94(1): 163; 1979.

The case of an 8-yr-old boy with Klinefelter's syndrome and sexual precocity due to a thoracic human chorionic gonadotropin (HCG)-producing teratoma is presented. The Klinefelter's syndrome was suspected because of a relative impairment of testicular enlargement in relation to plasma testosterone levels (0.35 $\mu\text{g}/\text{deciliter}$). This diagnosis was confirmed by the presence of testicular sclerohyalinization and by the karyotype (47 XXY). Plasma and tumor HCG levels were 25 milli-IU (mIU)/ml and 2,500 mIU/g, respectively. - 79-2331 Occurrence of Non-Hodgkin's Lymphoma after Therapy for Hodgkin's Disease.** (Eng) Krikorian, J. G. (Div. Medical Oncology, Dept. Medicine, Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Burke, J. S.; Rosenberg, S. A.; Kaplan, H. S. *N Engl J Med* 300(9): 452-458; 1979.

The clinical and pathologic features of six cases of non-Hodgkin's lymphoma (NHL) (diffuse undifferentiated in 4, diffuse histiocytic in 2) in patients treated with both radiation and chemotherapy for Hodgkin's disease (HD) were studied. Five of the six patients were among a study group of 579 HD patients that were prospectively followed since diagnosis. Five of the patients showed abdominal or gastrointestinal involvement with NHL. In no case was evidence of HD present when the NHL was diagnosed. In the study group, the actuarial risk of NHL at 10 yr was 4.4% and that of acute leukemia was 2.0 %. In the subgroup of patients receiving both radiation and chemotherapy, the actuarial risks of NHL and acute leukemia at 10 yr was 15.2% and 3.9%, respectively. Acute myelocytic leukemia occurred an av of 54 mo after the diagnosis of HD, whereas NHL occurred an av of 89 mo after the diagnosis. It is concluded that NHL may occur late in the course of treatment of HD and that, like acute leukemia, it may result from combined-modality therapy. (39 refs)

- 79-2332 Primary Malignant Liver Tumors: Association with Oral Contraceptives.** (Eng) Vana, J. (Dept. Epidemiology, Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Murphy, G. P. *NY State J Med* 79(3): 321-325; 1979.

Data on 149 women and 138 men with primary malignant liver tumors reported by 477 US hospitals during 1970-1975 were analyzed by sex, age, histologic diagnosis, and, in female patients, by history of oral contraceptive use. The malignant tumors were hepatocellular carcinoma (HCC: 84.6% and 80.4% in women and men, respectively), cholangiocarcinoma (8.7% and 14.5%), or combined HCC and cholangiocarcinoma (6.7% and 5.1%). Two male patients had a strong family history of liver tumors. Long-term use of alcohol was noted in eight male HCC patients, and two male patients had been under long-term treatment for ulcerative colitis. One male HCC patient (24 yr old) had been treated with androgen injections for infertility and another (29 yr old) had a history of uncorrected, undescended testis. Of the 126 HCC in women (15-45 yr old), a history of oral contraceptive use was found in 31% of patients; in the age group

26-35 yr, it was 43%. Significant ip hemorrhage occurred in 17% of the HCC in oral contraceptive users. The results of this survey neither confirm nor disprove an association between oral contraceptive use and malignant liver tumors. However, literature findings, ie, differences in the frequency of malignant tumors among users and nonusers of oral contraceptives in the reproductive age groups and certain similarities between benign and malignant liver tumors in users, warrant systematic review and follow-up of other large series of liver tumors. (36 refs)

- 79-2333 Effects of Long-Term Estrogen Replacement Therapy. II. Neoplasia.** (Eng) Hammond, C. B. (Duke Univ. Medical Center, P.O. Box 3143, Durham, NC, 27710); Jelovsek, F. R.; Lee, K. L.; Creasman, W. T.; Parker, R. T. *Am J Obstet Gynecol* 133(5): 537-547; 1979.

The effects of long-term estrogen therapy on the incidence of neoplasia were analyzed retrospectively in two groups of hypoestrogenic women that had been observed by a single group of physicians for at least 5 yr. One group (301 patients) had received replacement estrogen therapy for > 5 yr, and the other (309 patients) had received no estrogen treatment. In each group, 207 women had uteri in situ. Incidence figures for neoplasia (gynecologic, breast, and all sites) were compared between the two groups and with the Third National Cancer Survey, yielding a risk ratio for the development of adenocarcinoma of the endometrium among estrogen-treated women of 3.8 and 9.3, respectively. There was no increase among any other malignancies. The addition of synthetic progestin to the estrogen therapy provided significant protection against the likelihood of developing endometrial cancer and did not reduce previously reported metabolic benefits of estrogen treatment. Data pertaining to estrogen use and details of the patients with endometrial carcinoma (11 in the estrogen-treated group, 4 in the untreated group) are presented. (20 refs)

- 79-2334 A Case Control Study of Gastrointestinal and Urinary Tract Cancer Mortality and Drinking Water Chlorination.** (Eng) Alavanja, M. (Sch. Health Sciences, Hunter Coll., New York, NY, 10029); Goldstein, I.; Susser, M. *Water Chlorination* 2: 395-409; 1978.

To assess the potential cancer hazard associated with drinking chlorinated water, a case-control study was made of 3,446

people who died from gastrointestinal (GI) or urinary tract (UT) cancer in seven New York counties between 1968 and 1970 and 3,444 individually matched controls. There was a statistically significant excess of GI and UT cancer deaths among women living in urban areas of Erie County and among men living in urban areas of Erie and Rensselaer counties. Similar, but nonsignificant, trends were demonstrated for Schenectady and Allegany counties. GI and UT cancer deaths were significantly elevated among men and women in the chlorinated water areas of Erie and Schenectady counties and among men in the chlorinated water areas of Rensselaer county. Residents of Cattaraugus, Chautauqua, and St. Lawrence counties showed no excess GI or UT cancer mortality associated with living in urban or chlorinated water areas. Urban, but not rural, chlorinated water areas showed significantly increased mortality from lung cancer compared with nonchlorinated water areas. No correlation between GI and UT cancer mortality and inorganic ion concentrations was demonstrated. Voluntary reduction of the chloroform concentrations in potable water to $< 100 \mu\text{g/liter}$ is highly desirable. (7 refs)

79-2335 Epidemic Problems and Chlorination of Drinking Water and Sewage in the Federal Republic of Germany. (Eng) Muller, G. (Inst. Water, Soil and Air Hygiene, Federal Health Office, Berlin, W. Germany). *Water Chlorination* 2: 483-492; 1978.

Within the last 40 yr, there has been an approx 60% increase in all cancer-related deaths in West Germany. However, gastrointestinal and stomach cancers, the main types that might be induced by drinking water containing chlorinated organic compounds, have decreased. Statistics for regions using unchlorinated and slightly chlorinated drinking water showed the same trend as that found for the entire country. Thus, there is no evidence that chlorination of drinking water promotes cancer. (8 refs)

79-2336 A Study on the Aetiological Factors of Bilharzial Bladder Cancer in Egypt--1. Nitrosamines and Their Precursors in Urine. (Eng) El-Merzabani, M. M. (Dept. Cancer Biology, Cancer Inst., Cairo Univ., Cairo, Egypt); El-Aaser, A. A.; Zakhary, N. I. *Eur J Cancer* 15(3): 287-291; 1979.

The levels of nitrosamines (NA's) and their precursors in the urine of normal Egyptians and Egyptians with bilharzial infestations, bladder cancer, and other types of cancer were investigated. The urinary pH's were similar in all groups, whereas the thiocyanate levels were higher in the patients with bilharzial infestation and bladder cancer (34 and 39 ppm, respectively) than in those with no cancer or nonbladder cancer (21 and 24 ppm, respectively). Nitrate, which was present in the urine of 3/10 patients with bilharzial infestation and 7/15 patients with bladder cancer, was not present in the urine of

normal subjects and was present in the urine of only 1/14 subjects with nonbladder cancer. Endogenous NA's were present in urine samples from 2 normal subjects, 3 patients with bilharzial infestation, 15 patients with bladder cancer, and 6 patients with nonbladder cancer. After chemical nitrosation of the urine at pH 4, total NA's were $2,103$ and $2,314 \times 10^{-9}$ g/liter in the bilharzial and bladder cancer patients, respectively, compared with only 63.2 and 393×10^{-9} g/liter in the normal subjects and those with nonbladder cancer, respectively. Only in the urines from the bladder cancer patients could NA's be formed at pH 7. (11 refs)

79-2337 Comparison of Biochemical and Questionnaire Estimates of Tobacco Exposure. (Eng) Vogt, T. M. (Health Services Res. Center, Kaiser Foundation Hosps., 4610 S. E. Belmont St., Portland, OR, 97215); Selvin, S.; Hulley, S. B. *Prev Med* 8(1): 23-33; 1979.

The magnitude and independence of the association of 17 variables from a smoking questionnaire with levels of expired air CO and of serum thiocyanate (SCN) were determined by multiple regression analysis. The test cohort comprised 142 men (aged 35-57) enrolled in a multicenter coronary heart disease prevention study. The reported number of cigarettes smoked per day was the strongest questionnaire variable, and it accounted for 24% of the variation in the SCN + CO index. Only two other variables added significant information to the multiple regression--the time elapsed since last smoking (6%) and the longest time the smoker had ever quit (6%). The remaining 14 questionnaire variables together added 13% to the multiple regression of the SCN + CO index. The chief conclusion, which was confirmed by covariance analysis, is that questionnaire measures of dosage such as reported depth of inhalation, the amount of each cigarette smoked, and the use of filters may contain only trivial information on habitual tobacco exposure beyond that already available from reported smoking frequency. The CO and SCN analyses provide an objective and practical addition to estimates of tobacco exposure from questionnaire responses. (29 refs)

79-2338 A Study on the Aetiological Factors of Bilharzial Bladder Cancer in Egypt--2. Nitrosamines and their Precursors in Egyptian Dairy Products. (Eng) El-Aaser, A. A. (Dept. Cancer Biology, Cancer Inst., Cairo Univ., Cairo, Egypt); El-Merzabani, M. M.; Zakhary, N. I. *Eur J Cancer* 15(3): 293-298; 1979.

Milk, yoghurt, and four types of cheese consumed by Egyptians were analyzed for the presence of nitrosamines (NA's). NA's were not detected in blue cheese or yoghurt, and they were detected at low levels (3.2 and 9.7×10^{-9} in two milk samples. Contamination ranging from 20 to 160×10^{-9} g was found in 3/10 samples of cottage cheese, 7/10 samples of white cheese, and 6/9 samples of salted cheese. Only volatile NA's were detected in two samples of white cheese and three

of salted cheese ($20-40 \times 10^{-9}$ g). The optimum pH for the nitrosation of amines present in white and cottage cheese was 1 and 4, respectively and that for the blue and salted cheeses was 3. Chemical nitrosation yielded large amounts of extractable NA's in the samples. The highest levels were found in blue cheese, with $> 60\%$ of the NA's being volatile. The lowest levels were found in cottage cheese, with $> 50\%$ being volatile. Milk and yoghurt contained much lower concentrations of NA's, and most were not volatile. The daily consumption of salted cheese and drinking water with a high nitrate content, along with a heavily infected urinary bladder due to bilharzial infestation, might contribute to the high incidence of bladder cancer among Egyptian farmers. (19 refs)

- 79-2339 Statistical Analysis of Epidemiological Data from a Chromium Chemical Manufacturing Plant.** (Eng) Hill, W. J. (Buffalo Res. Lab., Allied Chemical Corp., 20 Peabody St., Buffalo, NY, 14210); Ferguson, W. S. *J Occup Med* 21(2): 103-106; 1979.

Probability window analysis was applied to the incidence of bronchogenic carcinoma in a group of chromium chemical manufacturing workers over the period 1929-1977. A significant downward trend in reported bronchogenic carcinoma was found that coincided with major process improvements made in 1951 (new bichromate plant) and 1961 (new chromic acid plant). Also, there have been no reported cases of bronchogenic carcinoma among persons who started their employment after 1957, even though one or more cases might have been expected from the local incidence in this age group. Because of the correlation over time between reduced incidence of bronchogenic carcinoma and lower chromium exposure levels, the improved working environment has to be considered a major contributing factor to the favorable trend. (7 refs)

- 79-2340 Mortality Study of Bleachers and Dyers.** (Eng) Newhouse, M. L. (TUC Centenary Inst. Occupational Health, England). *Ann Occup Hyg* 21(3): 293-296; 1978.

The causes of death among 1,429 men employed in the dyeing industry in Yorkshire, England, prior to 1936 and dying between 1957 and 1968 were studied. The results were compared with data from the general population at the relevant period. Approx two-thirds of the dye workers were 65 yr or older at death. There were small excesses due to cancer and respiratory diseases, but the differences between the observed and expected figures were not statistically significant. There was no indication of a particular risk in this group and no excess mortality from cancer of the bladder. (8 refs)

- 79-2341 A Dosage Response Curve for the One Rad Range: Adult Risks from Diagnostic Radiation.** (Eng) Bross, I. D. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Ball, M.; Falen, S. *Am J Public Health* 69(2): 130-136; 1979.

A new biostatistical technology to be used in the development of mathematical models for the relationship between radiation exposure and leukemia or other diseases is described. A dose-response curve for the exposure range between 100 millirads and 10 rads ("one rad range") was developed from data on men exposed to ordinary diagnostic radiation. The findings are based on approx 220 men with nonlymphatic leukemia and > 270 random-sample controls from the Tri-State Survey (New York, Maryland, and Minnesota). The new findings suggest that the estimates previously obtained by extrapolation from high-dose levels to low-dose levels underestimate the actual hazards by an order of magnitude. The new dose-response curves indicate that linear extrapolation fails because it disregards the subgroups in the general population that are particularly vulnerable to x-rays. There are immediate implications concerning the use of medical x-rays in screening or for routine purposes. The past risk-benefit calculations were based on extrapolative estimates, and they require drastic revision. Uses of x-rays that were previously marginal are now clearly contraindicated. (12 refs)

- 79-2342 Possible Induction of Basal Cell Carcinoma by External Alpha Radiation in Uranium Mine Workers.** (Cze) Sevcova, M. (Kozni oddeleni, ZUNZ Uranoveho prumyslu, Plzenska 77, 261 01 Pribram I., Czechoslovakia); Horacek, J.; Sevc, J. *Cas Lek Cesk* 117(46): 1442-1444; 1978.

The incidence of basal cell carcinoma of the skin was studied in uranium miners exposed to alpha radiation. The annual incidence of basal cell carcinoma was 7.65/10,000 in uranium miners exposed for 5-10 yr, vs an expected incidence of 0.63/10,000. For miners whose length of employment exceeded for 10 yr, the annual incidence was 13.15/10,000 vs an expected value of 0.67/10,000. The incidence was 1.08/10,000 (expected value 1.43/10,000) in uranium mine workers who were not involved in underground mining operations. The cumulated dose equivalent in the basal layer of the epidermis after long years of exposure proved to be $> 1,000$ roentgen-equivalents-man (rem). The av coefficient of risk per unit of dose equivalent was estimated to be 5×10^{-7} /rem/yr. (11 refs)

- 79-2343 Childhood Leukemias Associated with Fallout from Nuclear Testing.** (Eng) Lyon, J. L. (Dept. Family and Community Medicine, Univ. Utah Coll. Medicine, 50 N. Medical Drive, Salt Lake City, UT, 84132); Klauber, M. R.; Gardner, J. W.; Udall, K. S. *N Engl J Med* 300(8): 397-402; 1979.

Because of continuing concern over the possible carcinogenic effects of low-level radiation, the population of Utah was studied because of its exposure to fallout from 26 nuclear tests between 1951 and 1958. Certain rural counties (high-fallout counties) received most of the fallout during that period. All deaths from childhood cancers occurring in the entire state between 1944 and 1975 were reviewed and assigned to a cohort of either high or low exposure, depending on whether they were < 15 yr old between 1951 and 1958. For reasons unknown, leukemia mortality among the low-exposure cohort in the high-fallout counties was about half that of the US population and the population of the remainder of the state. Mortality increased by 2.44 times (95% confidence, 1.18 to 5.02) to just slightly above that of the US in the high-exposure cohort residing in the high-fallout counties, and it was greatest in 10- to 14-yr-old children. For other childhood cancers, no consistent pattern was found in relation to fallout exposure. The increase in leukemia deaths could be due to fallout or to some other unexplained factor. (23 refs)

79-2344 Primary Liver Cell Cancer in Britain - A Viral Aetiology? (Eng) Bassendine, M. F. (Dept. Medicine and Pathology, Royal Free Hosp., Hampstead, London NW3, England); Chadwick, R. G.; Lyssiotis, T.; Thomas, H. C.; Sherlock, S.; Cohen, B. J. *Br Med J* 1(6157): 166; 1979.

The incidence of hepatitis B virus (HBV) infection and alcoholism among 24 British Caucasians with primary liver cell cancer (PLCC) was studied. Nineteen of the patients were men, and the mean age was 55 yr. Sixteen patients were positive for HB core antibody. Six of these patients were positive for HB surface antibody. Thirteen of the 16 patients had histologic evidence of cirrhosis, and 7 gave a history of excessive alcohol intake. Eight patients showed no evidence of HBV infection. Of these patients, six had cirrhosis and four gave a history of excessive alcohol intake. Sixteen patients were positive for α -fetoprotein, the incidence being nonsignificantly higher among the HBV-positive patients. The data lend further support to the view that HBV is etiologically related to PLCC, although other factors must also be involved. (5 refs)

79-2345 Herpes Simplex in Gynecology and Obstetrics. (Eng) Bloomfield, R. (State Univ. New York, Downstate Medical Center, Box 1216, 450 Clarkson Ave., Brooklyn, NY, 11203); Suarez, J. R.; Roque, Z. S.; Tan-taksem, P. *J Natl Med Assoc* 71(2): 161-164; 1979.

A review of 79,357 Papanicolaou smears taken at a medical center revealed that 40 patients had cellular changes characteristic of herpetic infection. Eleven were pregnant and 29 were gynecologic patients. Four of the 40 patients also had cervical dysplasia. None of the 341 smears positive

for carcinoma of the cervix showed evidence of herpes. However, after the study was concluded, one patient with carcinoma in situ and herpes was seen. A parallel survey revealed that three infants died from disseminated herpes infections between 1972 and 1976. There is evidence in the literature to suggest a definite relationship between herpes simplex virus type 2 (HSV-2) and cervical cancer. HSV-2 can transform embryo fibroblasts in vitro, and it has been isolated from a cell line derived from carcinoma in situ. Higher titers of HSV antibody have been detected in patients with dysplasia, carcinoma in situ, and invasive carcinoma. (23 refs)

79-2346 The Orderliness of Cell Proliferation and Cell Differentiation in Relation to Kinetic Heterogeneity in Mouse Bone Marrow. (Eng) Shackney, S. E. (Clinical Pharmacology Branch, Div. Cancer Treatment, NCI, Bethesda, MD, 20014). *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 789-804; 1978.

Kinetic studies of transverse sections of male NIH mouse femoral marrow produced new information on hematopoietic cell proliferation and differentiation. A model was proposed that features a small fraction of rapidly proliferating stem cells in the subendosteal region, with central migration and growth retardation of many of these cells. Migrating cells may either differentiate or serve as a slowly proliferating reserve pool. The model features population size-dependent feedback control and cytomorphological correlates. The most rapidly proliferating cells are among the largest cells in the population; of these, the premitotic cells are the largest. As cells spiral through progressively longer cycles, they do not quite double in volume between divisions. This results in small av cell volumes among the slowly proliferating cells. (42 refs)

79-2347 Lymphoid Neoplasia Following Connective Tissue Disease. (Eng) Banks, P. M. (Dept. Surgical Pathology, Mayo Graduate Sch. Medicine, Rochester, MN); Witrak, G. A.; Conn, D. L. *Mayo Clin Proc* 54(2): 104-108; 1979.

A retrospective review of 29 patients seen between 1965 and 1975 was undertaken to determine whether there are distinctive histopathologic features of the lymphoid neoplasms that occur in patients with previous connective tissue disease [mainly rheumatoid (19) and psoriatic (4) arthritis]. The types of neoplasm included Hodgkin's disease (2 cases), diffuse large-cell lymphoma (11), nodular poorly differentiated lymphocytic lymphoma (1), diffuse poorly differentiated lymphocytic lymphoma (1), diffuse well-differentiated lymphocytic lymphoma (1), and chronic lymphocytic leukemia (6). Twenty-two cases showed neither immunoblastic nor plasmacytoid features. The time interval between the onset of connective tissue disease and that of lymphoid neoplasia in 29 patients ranged from 4 mo to 63 yr (mean, 15.4 yr). At

the time of diagnosis of the neoplasia, the connective tissue disease was inactive in 11 patients, mildly active in 8, and moderately or severely active in 10. The data fail to confirm a relationship between lymphoid proliferations with immunoblastic morphology and connective tissue diseases. (17 refs)

- 79-2348 Lymphoma and Rheumatoid Arthritis (Letter to Editor).** (Eng) Isomaki, H. (Rheumatism Foundation Hosp., 18120 Heinola 12, Finland); Hakulinen, T.; Joutsenlahti, U. *Lancet* 1(8112): 392; 1979.

The incidence of malignancies in Finnish rheumatoid arthritis (RA) patients was higher than that expected in men (407 vs 354.1) but as expected in women (795 vs 783.8). The incidence of leukemia, lymphoma, Hodgkin's disease, and myeloma was 130, significantly higher ($p < 0.001$) than that expected (59.6). The continuous immunological stimulation in RA could cause proliferation and malignant transformation of some clones of immunologically competent cells. Immunodeficiency might also be involved. (3 refs)

- 79-2349 A Cluster of Osteogenic Sarcomas in Time and Space.** (Ger) Sauer, E. (I. Mediz. Klinik der Techn. Universitat, Ismaninger Strasse 22, D-8000 Munich, 80, W. Germany); Fink, U.; Theiss, W.; Rastetter, J. *Munch Med Wochenschr* 121(10): 343-344; 1979.

Four cases of osteogenic sarcoma (OGS) were diagnosed within 10 mo in people living within 17 kilometers of each other. This is believed to be the first report of a cluster of OGS in both space and time. The tumors occurred in two brothers who shared a house, and in two unrelated girls who were friends of the brothers. The first sarcoma (Case I) was found in a 21-yr-old man who presented with a swelling below the knee. An OGS of the head of the tibia was diagnosed histologically. He remains recurrence-free 6 yr after amputation was performed. Five months after the diagnosis of OGS in this patient, his 16-yr-old brother (Case II) presented with a swollen knee. Symptomatic treatment was given for 2.5 mo without improvement. OGS of the distal head of the femur was diagnosed by x-rays and by histologic criteria after amputation. Lung metastases were found 3 mo after surgery, and the patient died 4 mo later with multiple lung metastases. Case III involved a 13-yr-old girl who went to school with a brother of Cases I and II. She experienced sudden pain in a knee joint 10 mo after the diagnosis of Case I. A histological diagnosis of OGS was made 1 mo later. She died with lung metastases 1 yr later. The fourth OGS was diagnosed in a 17-yr-old girl who experienced knee pain 5 mo after the diagnosis of Case I. She was treated with radiation, amputation, and chemotherapy but died with lung metastases 2 yr later. The clustering of these cases suggests the action of an infectious agent in development of OGS. (no refs)

- 79-2350 Scar Cancer of the Lung. Increase Over a 21 Year Period.** (Eng) Auerbach, O. (Veterans Admin. Hosp., E. Orange, NJ, 07019); Garfinkel, L.; Parks, V. R. *Cancer* 43(2): 636-642; 1979.

The incidence of peripheral lung tumors related to scars among 7,629 autopsies performed in one hospital during 1955 through 1975 was studied. Lung cancer was found in 1,186 cases, 82 of which were peripheral cancers associated with scars. The number of scar cancers increased progressively from 1.8% of all lung cancers during 1955 through 1959 to 15.9% during 1970 through 1975. Forty-five percent of all peripheral lung cancers originated in a scar, with most of the scar cancers being classified as adenocarcinomas. Of the scar cancers, 56.1% were associated with an infarct, 23.2% with tuberculosis, 1.2% with granulomas, and 1.2% with asbestosis. The upper lobes of the right and left lungs were involved almost equally, and they contained 76.8% of all scar cancers. Among smokers the percent of scar cancers did not increase with the number of cigarettes smoked, and there was no apparent correlation with occupational category or with age at death. The most common sites of metastasis of all peripheral tumors (including scar tumors) were the regional lymph nodes, adrenals, liver, brain, bone, and distal lymph nodes, in that order. (23 refs)

- 79-2351 Primary Hemochromatosis and Cancer of the Esophagus.** (Spa) Curto Cardus, J. A. (Servicio de Patologia Digestiva 'A', Hospitalet de Llobregat, Barcelona, Spain); Varas Lorenzo, M. J.; Novell Sala, V.; Sirvent Calvera, J. *Rev Esp Enferm Apar Dig* 54(3): 279-288; 1978.

In a series of 211 patients with esophageal cancer, an association between esophageal cancer and primary hemochromatosis was found in 2 men (aged 75 and 51 yr, respectively). They were heavy drinkers, and one was also a heavy smoker. Both were diagnosed with differentiated keratinizing squamous epithelial carcinoma. Pulmonary tuberculosis and esophageal varices were also found in one of the men. This is the first reported association of primary hemochromatosis and esophageal cancer. (21 refs)

- 79-2352 Gastric Carcinoma and Previous Peptic Ulceration.** (Eng) Ellis, D. J. (Queen Elizabeth Hosp., Queen Elizabeth Medical Centre, Edgbaston, Birmingham, England); Kingston, R. D.; Brookes, V. S.; Waterhouse, J. A. *Br J Surg* 66(2): 117-119; 1979.

The incidence of gastric carcinoma patients that had a previously diagnosed or suspected peptic ulcer was determined by an analysis of two English studies. These studies were the West Midlands Gastric Chemotherapy Trial (1974-1976) and a retrospective study of patients presenting to the United Birmingham Hospitals with gastric carcinoma during 1958-1962 and 1968-1972. Of the total 1,026 patients, 55 had previously

undergone surgery for duodenal ulcer. A further 33 patients had a duodenal ulcer confirmed at the time of operation for carcinoma, at postmortem, or by previous radiological studies. The confirmed incidence of previous duodenal ulcer was therefore 8.6%. In addition, 51 patients had a history of dyspepsia typical of duodenal ulcer at least 5 yr before the onset of symptoms referable to carcinoma. The mean time interval between surgery for a duodenal ulcer and the development of gastric carcinoma was much longer following a partial gastrectomy (mean 24 yr) than following vagotomy and drainage (6 yr). Only 12 patients had evidence of gastric ulcer. (27 refs)

- 79-2353 Diet and Large-Bowel Cancer in Three Socio-economic Groups in Hong Kong (Letter to Editor).** (Eng) Hill, M. (Central Public Health Lab., London NW9, England); MacLennan, R.; Newcombe, K. *Lancet* 1(8113): 436; 1979.

A Hong Kong study demonstrated that colorectal cancer mortality was positively correlated with socioeconomic group and that the incidence among men in the highest income group was over twice that among men in the lowest income group. Fecal bile acid concentration was also correlated with socioeconomic group. The high-income group consumed more food of all types and higher amounts of fiber than the low- and middle-income groups. (19 refs)

- 79-2354 Mortality for Stump Cancer after Gastric Resection for Peptic Ulcer.** (Eng) Cheli, R. (Dept. Gastroenterology, Inst. Oncology, Ospedali Civili Genova, Genoa, Italy); Santi, L.; Molinari, F.; Ciancamerila, G.; Puntoni, R. In: *Prevention and Detection of Cancer. Part II. Detection. Vol. 1. High Risk Markers. Detection Methods and Management.* Nieburgs, H. E., ed. (New York: Marcel Dekker): 1299 pp.; 93-96; 1978.

The incidence of gastric stump cancer in patients who had undergone partial gastrectomy for gastric (337 patients) or duodenal (180 patients) ulcer between 1948 and 1967 was evaluated statistically. The observed mortality rate for gastric stump cancer was 7/337 patients operated on for duodenal ulcer (vs 4.1 expected) and 9/180 patients operated on for gastric ulcer (vs 3.9 expected). Compared with the general population aged > 45 yr, mortality from gastric cancer was significantly increased among patients who had undergone resection for gastric ulcer and nonsignificantly increased among patients who had undergone resection for duodenal ulcer. When the case material was analyzed following subdivision into person-years by age group, there was a highly significant increase in mortality from gastric stump cancer in both patient groups. The data support the hypothesis that the epithelial metaplasia developing early in a resected stomach may represent a condition similar to that of atrophic gastritis, both conditions being associated with a high risk of cancer. (9 refs)

- 79-2355 A Prospective Study of the Relationship Between Benign Breast Diseases and Breast Carcinoma.** (Eng) Coombs, L. J. (Div. Biostatistics and Epidemiology, Georgetown Univ. Sch. Medicine, Washington, DC, 20007); Lilienfeld, A. M.; Bross, I. D.; Burnett, W. S. *Prev Med* 8(1): 40-52; 1979.

Using a prospective approach, 747 women (15-69-yr old) diagnosed with benign breast disease (BBD) during 1957-1965, and a matched control group were followed for subsequent breast cancer (BC) development. The age-adjusted cancer mortality rate was 1.4 times higher in the BBD group than in the controls, and the age-adjusted BC mortality rate was 4.7 times higher. The BBD group also had a higher incidence rate for all cancers combined than the control group. The relative risk of BC among women with BBD was 3.0 compared with the control women. Similar to the mortality data, the differences in the overall incidence of cancer were primarily due to the higher incidence of BC in the BBD group, since the incidence of cancers other than BC was similar in the two groups. In the BBD group, women having their natural menopause at age 50 or later had a relative BC risk of 9.6. The risk associated with BBD among women having natural menopause prior to age 50 was 3.7, compared with 2.5 among women without BBD having natural menopause at age 50 or later. The relationship between BBD and BC is probably indirect, in that both BBD and BC may be the result of a similar abnormal hormonal status. BBD may simply be an earlier manifestation of this abnormal state. (34 refs)

- 79-2356 Incidence of Malignant Neoplasms of All Types in Patients with Graves' Disease.** (Eng) Munoz, J. M. (Section Publications, Mayo Clinic, 200 First St. SW, Rochester, MN, 55901); Gorman, C. A.; Elveback, L. R.; Wentz, J. R. *Arch Intern Med* 138(6): 944-947; 1978.

The incidence of malignancy among 342 Olmsted County, Minnesota residents diagnosed with Graves' disease between 1935 and 1967 was determined. During 4,736 person-years of observation, 32 malignancies were diagnosed; 24 cases were expected and the difference is not significant. Four cases of breast carcinoma were found vs five expected. Other tumor sites were cervix (5), uterus (2), rectosigmoid colon (3), stomach (2), larynx (2), and lung (2). There were three cases of leukemia, and in nine other sites one cancer each was recorded. There was a slightly higher than expected incidence of malignancy in patients who had received ¹³¹I therapy; this finding requires further study in a larger patient population. Among patients who received thyroid hormone, the observed incidence of breast cancer was not significantly different from the expected incidence in this population. (29 refs)

- 79-2357 Statistics of Leukemia Morbidity in Krakow Province, Poland, in 1951-1968.** (Rus) Ianitskii, K. (Hematological Clinic, Inst. Therapy, Krakow, Poland);

Slivchinskaia, B. *Probl Gematol Pereliv Krovi* 24(3): 38-40; 1979.

Between 1951 and 1968, leukemia was diagnosed in 1,846 patients in the province of Krakow, Poland. Calculation of the morbidity rates (per 100,000) for various variants of leukemia in the total population and in the age groups <15, 15-44, and >45 yr showed that there was a significant increase in the incidence of chronic myeloid leukemia (from 0.5 in 1951 to 2.4 in 1968), chronic lymphoid leukemia (from 0.8 to 3.8), and acute leukemia (from 1.1 to 5.33). Overall leukemia morbidity was increased in the age groups 15-44 and >45 yr (from 1.5 to 4.68 and from 3.8 to 6.24, respectively), but it was decreased in the <15-yr-old age group (from 2.7 to 1.42). (20 refs)

79-2358 Burkitt's Lymphoma in Ghana: Urban-Rural Distribution, Time-Space Clustering and Seasonality. (Eng) Biggar, R. J. (Burkitt's Tumor Project, P. O. Box 194, Accra, Ghana); Nkrumah, F. K. *Int J Cancer* 23(3): 330-336; 1979.

Epidemiologic data from 236 patients with Burkitt's lymphoma (BL) and 103 patients with non-Burkitt's lymphoma (NBL) seen between 1970 and 1975 at a hospital in Accra, Ghana, are presented. The av age for both BL and NBL patients was 7-8 yr. The male:female ratio was 1.7:1 for BL and approx 1:1 for NBL. One hundred and three of Ghana's 141 census districts were represented in the study group. There was no apparent relationship between case distribution and rainfall, and there was no seasonal variation in date of onset of symptoms or referral date. No evidence of time-space clustering was obtained. Two observations suggested a higher incidence of BL among rural vs urban populations: there were lower referral rates from all areas of >10,000 population compared with more rural communities, and there were more BL referrals than NBL referrals from small communities. Significantly more BL patients than NBL patients had fathers whose occupation was farming. There were no other significant differences related to social or economic factors. The higher risk of BL among rural dwellers is consistent with severe malaria being a factor in the etiology of BL. (18 refs)

79-2359 Incidence of Malignant Lymphoma in Hawaii. (Eng) Oishi, N. (Cancer Center Hawaii, Univ. Hawaii, Honolulu, HI); Rashad, M. N. *In: Prevention and Detection of Cancer. Part II. Detection. Vol. 1. High Risk Markers. Detection Methods and Management.* Nieburgs, H. E., ed. (New York: Marcel Dekker): 1299 pp.; 75-79; 1978.

The incidences of malignant lymphoma among the racial groups living in Hawaii during 1968 through 1972 were compared. The av annual age-race-adjusted incidence rate per 100,000 for non-Hodgkin's lymphoma was 4.9 for men and 4.6 for women. The incidence rate per 100,000 for Hodgkin's

disease was 2.4 for men and 1.6 for women. Hawaiians and Caucasians had higher incidence rates than other racial groups for Hodgkin's disease and non-Hodgkin's lymphoma and higher death rates than other racial groups for Hodgkin's disease. Filipinos had the highest death rates for the non-Hodgkin's lymphomas. The male:female ratio for non-Hodgkin's lymphoma varied from 0.2 for the Chinese to 1.6 for the Filipinos, and the ratio for Hodgkin's disease varied from 1.2 for the Japanese to 3.4 for the Hawaiians. Hawaii provides a good location for studying the epidemiology of certain types of malignancy. (15 refs)

79-2360 The Natural History of Oral Leukoplakia. (Eng) Mehta, F. S. (Basic Dental Res. Unit, Tata Inst. Fundamental Res., Homi Bhabha Road, Bombay 400 005, India); Hamner, J. E.; Pindborg, J. J. *In: Prevention and Detection of Cancer. Part II. Detection. Vol. 1. High Risk Markers. Detection Methods and Management.* Nieburgs, H. E., ed. (New York: Marcel Dekker): 1299 pp.; 83-91; 1978.

The natural histories of oral leukoplakia (LP), other possible oral precancerous lesions, and oral cancer were studied in an epidemiologic survey of 50,915 adults in India. The incidence rate for LP was 2.1/1,000 men and 1.6/1,000 women, the peak incidence rate being in the age group 55-64 yr among men and in the age group 45-54 yr among women. The incidence was zero among individuals who did not use tobacco and was highest (5.3/1,000) among those who both chewed 'pan' (a combination of betel leaf, lime, areca nut, and tobacco) and smoked 'bidi' (coarse tobacco rolled in a dry temburni leaf). Among tobacco users, bidi smokers exhibited the lowest incidence rate (1.0/1,000). Ten oral cancers (squamous cell carcinoma) were detected among individuals with LP; four were found among those with no oral lesions. The rate of malignant transformation of LP was zero among those aged <35 yr, 5.5/1,000 among those aged 35-54 yr, and 13.7/1,000 among those aged ≥55 yr. The rate of malignant transformation was twice as high for women (11.1/1,000) as for men (5.1/1,000) and twice as high for tobacco chewers (11.5/1,000) as for those who chewed and smoked (6.4/1,000). Malignant transformation was not observed among those who only smoked. The data suggest that LP's associated with different tobacco habits may have different natural histories. (5 refs)

79-2361 A Methodological Investigation of Fatal Disease Risks in a Large Industrial Cohort. (Eng) Decoufle, P. (Environmental Epidemiology Branch, NCI, Bethesda, MD, 20014); Thomas, T. L. *J Occup Med* 21(2): 107-110; 1979.

Proportionate mortality analyses of 2,843 deaths among white male workers employed at a single large industrial

plant during 1938-1967 were performed to examine variations in estimates of fatal disease risks between deceased retirees (retiree deaths) or workers who died within 1 yr of last employment at the plant (active deaths) and workers who died at least 1 yr after leaving the plant (other deaths). The major potential hazardous exposure in the plant was oil mist. Risk estimates were based on the proportionate mortality ratio (PMR) of observed deaths to age- and calendar year-adjusted expected deaths derived from general population mortality. When the results for specific malignant neoplasms were analyzed, the PMR's for most site categories were similar for the active and retiree groups combined and the other group. However, the results for respiratory cancer indicate about a 50% increase among active and retiree deaths (PMR = 1.58) and near expected mortality in the other group (PMR = 1.08). When the results for persons dying within 1 yr of last employment were analyzed separately, a 25% increase in the relative frequency of cancer deaths was seen that might suggest that this subgroup was at special risk of cancer. However, the PMR's overstate the true risk for actively employed workers, since their mortality rate is generally lower than that of the general population. In any event, these results may indicate the expected magnitude of cause-specific PMR's in an industrial population with no extraordinary fatal disease risks. Thus, in examining cancer risks among actively employed workers using the PMR approach, it may be more appropriate to judge the observed PMR for total cancer in relation to an expected PMR greater than unity (possibly in the neighborhood of 1.25). This would imply that PMR's for cancer may have to be unusually high before one can conclude that a real increase in risk exists. (17 refs)

- 79-2362 Does Driving Cause Cancer and Diabetes?** (Eng) Robinson, A. A. (16 Quayle St., Sandy Bay, Hobart, 7005 Tasmania, Australia). *Med Hypotheses* 5(1): 175-184; 1979.

The relationship between deaths due to lung cancer, diabetes, and breast cancer and parameters representative of the influence of motor vehicle travel was examined using Australian data for the period 1920-1972. An examination of the correlation between numbers of deaths due to the three diseases and motor vehicle usage per 100,000 of population revealed that these diseases are directly linked to vehicle travel rather than to the effect of pollution. Vehicle travel may produce effects on the circulatory or nervous system that are common to the three diseases. It is hypothesized that the process of traveling in a motor vehicle, particularly driving, entails the covering of distance with minimal expenditure of body energy. In the human body, the perception of motion is controlled mainly by the eye. Having received visual information, the brain controls the supply of fuel for activities such as walking or running. If body energy is used for these activities, the level of unburned fuel in the blood is minimal. However, traveling without the expenditure of energy overloads the mechanism of control and gives rise to abnormally high levels of glucose,

fatty acids, etc, in the blood, which could be related to the increased deaths due to lung and breast cancer and diabetes. A study that partially support this hypothesis is summarized. (5 refs)

- 79-2363 A Survey of Neoplastic Disease in Oklahoma Native American Aborigines.** (Eng) Skye, G. E. (Oklahoma Medical Res. Foundation, Oklahoma City, OK); Hampton, J. W. In: *Prevention and Detection of Cancer. Part II. Detection. Vol. 1 High Risk Markers, Detection Methods and Management.* Nieburgs, H. E., ed. (Marcel Dekker, Inc.: New York): 1299 pp.; 47-56; 1978.

The incidences of neoplastic and other diseases among the white and native American (American Indian) populations of Oklahoma were compared for the years 1955 through 1959 and 1970 through 1974. The white population of Oklahoma comprises 90% of the total. During the 20-yr period, there was no change in the cancer incidence rate among the Indians. The cancer mortality rate among the Indians was only 68% of that among the white population: death from pulmonary, breast, esophageal, rectal, and intestinal cancers occurred less frequently among Indians than whites; death from stomach cancer occurred at approx the same rate; and death from cervical cancer occurred two times more frequently among the Indians. During 1955-1959, cervical cancer mortality was 3.3 times more frequent among Indians than among whites, whereas during 1970-1974, the cervical cancer mortality rates were approx equal in the two populations. Lung cancer mortality increased in both populations over the 20-yr period, but the increase was only 0.5-fold among the Indians compared with 2.5-fold among the whites. The results suggest that the long association of the North American Indian with tobacco may not have an ethnic protective factor. (5 refs)

- 79-2364 Tumours in Iceland. I. Malignant Tumours of Skin--A Histological Classification.** (Eng) McKnight, C. K. (Dept. Pathology, Univ. Iceland, Reykjavik, Iceland); Magnusson, B. *Acta Pathol Microbiol Scand (A)* 87(1): 37-44; 1979.

To investigate the pattern and incidence of primary skin malignancies in Iceland, 485 primary malignant skin tumors submitted for histologic diagnosis in Iceland during 1955 to 1974 were typed according to the World Health Organization classification. Of the tumors in men, 66.8% were basal cell carcinomas (BCC), 22% were squamous cell carcinomas (SCC), and 7.2% were malignant melanomas (MM). Of the tumors in women, 66.9% were BCC, 20.8% were MM, and 10.2% were SCC. The male:female ratio for all skin tumors was 1.2:1. The commonest sites for BCC and SCC were the head and neck, followed by the trunk for BCC and the hand for SCC. The commonest site for MM was the lower limb, followed by the head and neck. Primary skin malignancies

were uncommon before middle age, but they increased sharply to a max of 107/100,000 among women and 150/100,000 among men in the eighth decade of life. The incidence of BCC among women increased significantly from 1955-1964 to 1965-1974. There were no other significant changes in incidence. The pattern observed conforms to the established pattern of a decrease in incidence associated with increased latitude and decreased exposure to direct sunlight. The similarity in the rates for men and women suggests that length of exposure is more erratic in inducing malignancy at a low intensity of radiation than at a high intensity. (12 refs)

- 79-2365 The Role of Demographic Risk Factors in Carcinogenesis.** (Eng) Rose, E. F. (Toxicology Dept. Natl. Inst. Nutritional Disease, South African Medical Res. Council, P.O.B. 192, East London 5201, South Africa). In: *Prevention and Detection of Cancer. Part II. Detection. Vol 1. High Risk Markers. Detection Methods and Management.* Nieburgs, H. E., ed. (Marcel Dekker, Inc.: New York): 1299 pp.; 25-45; 1978.

Some of the demographic risk indicators that might participate in promoting esophageal carcinogenesis in the Transkei, southern Africa, are defined. Significantly increased rates of esophageal cancer, based on observed vs expected incidence, were found in association with high population density, elevations between 1,000 and 3,000 ft above sea level, Beaufort sedimentary strata, leached-out soil, low rainfall, and Eastern Province thorn veld and high veld-sourveld-dohne veld types. The incidence rates were lowest in areas of low population density and high rainfall and in those areas covered by dolderite. The sex and age distribution were not significantly different in low- and high-incidence areas. (17 refs)

- 79-2366 Multiple Primary Cancers Involving the Esophagus and the Head and Neck Region.** (Jpn) Ikeda, H. (Dept. Radiology, Osaka Univ. Hosp., Osaka, Japan); Miyata, Y.; Masaki, N.; Shigematsu, Y.; Inoue, T. *Gan No Rinsho* 25(2): 84-88; 1979.

Among the total 327 esophageal carcinoma patients registered in a Japanese hospital between 1967 and 1976, 36 (34 men, 2 women; 30 aged 50-69 yr) also had primary cancers of other organs. A total of 40 sites were involved; four of the patients had three primaries. The most common site of the other primaries was the head and neck region (30 sites, 26 patients). The remaining patients had cancer of the stomach (6), skin (2), prostate (1), and kidney (1). Carcinomas of the hypopharynx (10) and oropharynx (4) generally developed before (4) or synchronously (6) with the esophageal cancer, and patients died from esophageal or pharyngeal carcinoma in equal proportions. In patients with laryngeal (7), tongue (5), and oral cavity cancers (3), the esophageal cancer followed the development of these primaries and was the usual

cause of death. Five of the stomach cancers preceded (2) or were synchronous (3) with the development of the esophageal cancer. (12 refs)

- 79-2367 Carcinoma of the Gallbladder and Extrahepatic Biliary Ducts in Rochester, Minnesota, 1935-1971.** (Eng) Maram, E. S. (Sch. Veterinary Medicine, Pahlavi Univ., Shiraz, Iran); Ludwig, J.; Kurland, L. T.; Brihan, D. D. *Am J Epidemiol* 109(2): 152-157; 1979.

The epidemiology of carcinoma of the gallbladder and extrahepatic biliary ducts in Rochester, Minnesota, was studied using the Mayo Clinic record system. Fifty-two cases of carcinoma of the gallbladder and/or extrahepatic biliary ducts were diagnosed between 1935 and 1971, 36 cases in women and 16 in men. The mean annual incidence rate/100,000 population was 4.4 (3.1 for men and 5.4 for women). Of the 16 extrahepatic bile duct tumors, all were adenocarcinomas. Of the 36 gallbladder neoplasms, 30 were adenocarcinomas, 4 squamous cell carcinomas, and 2 adenoacanthomas. The anatomic distribution of initial lesions at diagnosis differed between the sexes: 78% of those in women were in the gallbladder, vs 25% in men; extrahepatic biliary ducts were the initial site of malignancy in 69% of men and 14% of women. During the study period, the incidence rate of carcinoma of the gallbladder and extrahepatic bile ducts did not change significantly in men, but it decreased significantly in women. The incidence rate increased with age in both sexes. For the 51 known deaths, the death certificates listed carcinoma of the gallbladder and/or extrahepatic biliary ducts as the underlying cause of death in 39 cases and as a contributory cause in 3. The frequencies of gallstones in women (75%) and men (62%) were significantly higher than expected. (20 refs)

- 79-2368 Doubts About Carpet Factory-induced Colonic Cancer (2 Letters to Editor).** (Eng) Wen, C. P. (17611 Turtle Creek, Houston, TX, 77090); Tsai, S. P.; Vobecky, J.; Devroede, G. *Gastroenterology* 76(3): 656-657; 1979.

Six specific criticisms are made of data collection and misclassification in an article concerning the high risk of colorectal cancer in carpet factory workers. In response, data are presented that substantiate a relative risk, during 1971-1975, of 9.6 for colorectal cancer in the population of workers in a carpet factory. (1 ref)

- 79-2369 Carcinoma of the Colon: Epidemiology, Etiology, Diagnosis, and Treatment.** (Eng) Diggs, C. H. (Dept. Medicine, Univ. Maryland Sch. Medicine, 22 South Greene St., Baltimore, MD, 21201). *Am J Med Sci*

277(1): 4-16; 1979.

The epidemiology, etiology, diagnosis, and treatment of colon cancer (CC), the second most common malignancy (after skin cancer) in men and women combined, are reviewed. Two case reports that typify the clinical presentation of CC are presented. Peak incidence occurs between age 50-70. Patients may present with a variety of symptoms, and these symptoms can usually be related to the site of involvement. A right-sided abdominal mass may be the presenting feature of right-sided tumors, constipation or change in stool caliber that of left-sided tumors. Other common symptoms are bloody stools, diarrhea, abdominal pain, tenesmus, mucus in stools, anorexia, and wt loss. However, many patients are symptom-free and have their disease detected on routine exam. CC is suggested to be a disease of Western civilization, since its incidence is much greater in Western Europe and the US than in African countries or Japan. Both fat intake and fiber intake probably act together or independently to cause the increased incidence of CC in Western countries. Compounds known to induce CC in laboratory animals are listed, as are substances that modify these chemically induced tumors. Disulfiram, selenium, sodium diethyl dithiocarbamate, and several pesticides appear to decrease the number of CC produced by carcinogens. It is postulated that intake of high amounts of dietary fat increases the level of cholesterol in the bile as well as the amount of bile acids. These compounds then travel to the large intestine where they are acted upon by intestinal bacteria with enzyme activities under dietary control. As a result, carcinogens that act directly on the bowel mucosa may be formed. Dietary fiber may also interact in some fashion. Methods of screening high-risk populations are described. (62 refs)

- 79-2370 A Case-Control Study of Relationships of Diet and Other Traits to Colorectal Cancer in American Blacks.** (Eng) Dales, L. G. (Dept. Medical Methods Res., Permanente Medical Group, 3700 Broadway, Oakland, CA, 94611); Friedman, G. D.; Ury, H. K.; Grossman, S.; Williams, S. R. *Am J Epidemiol* 109(2): 132-144; 1979.

Ninety-nine black patients (52 women, 47 men) with colorectal adenocarcinoma and 280 matched controls from hospitals and multiphasic health checkup clinics were interviewed about past dietary habits and other traits. Colon cancer patients (72) tended to report less frequent use of foods with at least 0.5% fiber content than did their controls. This relationship, although small and not statistically significant, showed a consistent dose-response gradient, appeared in both case-hospital control and case-multiphasic health checkup control comparisons, and could not be accounted for by the effects of other variables. Colon and rectosigmoid junction cancer patients (77) tended to have eaten foods with at least 5% saturated fat somewhat more often than controls. When consumption of these two groups of foods was considered in combination, significantly more colon cancer patients than controls reported a high-saturated fat foods-low-fibrous

foods eating pattern. In contrast to other studies, beef consumption showed a nonsignificant negative relationship with cancer. Statistically significant excesses were also calculated for the colorectal cancer patients in the following areas: cigar smoking of > 20 yr in men, nulliparity in women, and history of colorectal polyps. The relative excess colon cancer risk associated with the combined high-saturated fat-low-fiber dietary pattern exceeded the sum of the relative excess risks when evaluated individually, suggesting a synergistic interaction of the effects of saturated fats and low-fiber food on colon cancer risk. (31 refs)

- 79-2371 Epidemiology of Cancers: I. Cancerous Diseases of the Large Bowel.** (Eng) Schwarz, K. (Dept. Preventive and Community Medicine, Christchurch Clinical Sch., Christchurch, New Zealand); McDonald, M.; Malpress, W. *NZ Med J* 87(613): 387-390; 1978.

The pilot phase of an epidemiological study of large bowel cancer in Canterbury, New Zealand, is described. The study group comprised 312 patients diagnosed with colon cancer during 1970-1972. The main categories studied were (1) demographic factors, (2) anatomical scope of the colon cancers, (3) tumor classifications, and (4) symptoms and signs of the cancer onset and preceding disease episodes. Men outnumbered women except in two age groups, 45-49 and 70-74. Demographic characteristics were not significantly different between the colon cancer patients and the general population. Tumor classification did not seem to be of value in an epidemiological context. Anemia was present in 52.9% of the patients, rectal bleeding in 43.3%, and changes in bowel habits (constipation and diarrhea) in 80%. The major pathologies were diverticulitis (19.8%), polyps (10.8%), gallstones (9.2%), hemorrhoids (7%), cholecystitis (6.4%), and gastric ulcer, duodenal ulcer, ulcerative colitis and colitis (2.2% each). Other pathologies included thyroid disease (7.3%) and cervical cancer (3.5%). An abdominal mass was palpable. Most of the tumors were located in the sigmoid colon (38.4%), cecum (14.7%), and transverse colon (9.8%). (8 refs)

- 79-2372 Choriocarcinoma Following Term Pregnancy.** (Eng) Miller, J. M. (Southwestern Regional Center Trophoblastic Disease, Dept. Obstetrics and Gynecology, Duke Univ. Medical Center, Durham, NC, 27710); Surwit, E. A.; Hammond, C. B. *Obstet Gynecol* 53(2): 207-212; 1979.

Experience in treating 265 patients with malignant trophoblastic disease who were admitted to the Southeastern Trophoblastic Disease Center at Duke University Medical Center between July 1966 and June 1976 is reported. Twenty of these patients had choriocarcinoma following a term gestation and their survival rate was 60%, compared with a 95% survival rate for the remaining 245 patients. Previously de-

scribed risk factors of initial human chorionic gonadotropin titer of $> 100,000$ IU/24-hr urine, duration of symptoms for > 4 mo, significant prior unsuccessful chemotherapy, or cerebral or hepatic metastases identified the poor prognosis group. Postterm gestation poor prognosis patients had a significantly lower cure rate (47%) than other patients with a poor prognosis for gestational trophoblastic disease (75%; $p < 0.05$). Postterm gestation choriocarcinoma has a propensity for more extensive metastatic spread and would appear to be less responsive to conventional chemotherapy; this may be due to an altered immune response in these patients. It is suggested that an antecedent term pregnancy should be added to the previously described high-risk factors for patients with malignant trophoblastic disease. (21 refs)

- 79-2373 US Cancer Incidence and Mortality in the First Year of Life.** (Eng) Bader, J. L. (Clinical Epidemiology Branch, NCI, Rm A521 Landow Bldg., Bethesda, MD, 20014); Miller, R. W. *Am J Dis Child* 133(2): 157-159; 1979.

Data from the Third National Cancer Survey were used to evaluate the incidence of and mortality from cancer in infants aged < 1 yr between 1969 and 1971. A total of 196 tumors were diagnosed in 195 patients, the overall incidence being 183.4 per million live births. The mortality rate from cancer was 52.7 based on 2,044 deaths. The incidence was 35% higher in males than in females and 28% higher in whites than in blacks. Half of the cancers were found on the first day of life and two-thirds were found during the first week. Based on incidence, the most common tumor was neuroblastoma, followed by leukemia, kidney tumors, sarcomas, retinoblastoma, and CNS tumors. When mortality before 1 yr of age was used as an indicator of frequency, leukemia was ranked first, followed by neuroblastoma, CNS tumors, and tumors of the kidney. Differences in rank order based on mortality and incidence were due largely to differences in survival due to treatment. Cancer present at or soon after birth presents an opportunity to study causal factors that become less evident when a longer interval is involved. (27 refs)

- 79-2374 Clinical Statistics of Pediatric Urology at a Japanese Hospital from 1968 to 1977.** (Jpn) Takamatsu, M. (Dept. Urology, Wakayama Medical Coll., Wakayama, Japan); Kitagawa, M.; Morimoto, S.; Ogawa, T.; Ohkawa, T. *Acta Urol Jpn* 24(12): 1075-1081; 1978.

From 1968 to 1977, 3,789 children (2,870 males, 919 females) were treated at the urology department of a Japanese hospital. These patients comprised 15% of all the urological patients seen during this period. Congenital disorders (722 males, 76 females; 29.4%), nonspecific inflammatory diseases (438, 176; 22.6%), and functional urinary disturbances (323, 190; 18.9%) were the most common diseases. Twenty-nine of the children had tumors, 24 of which were malignant. They

included Wilms' tumor (9 patients), neuroblastoma (6), retroperitoneal lymphangioma (1), retroperitoneal teratoma (1), testicular tumors [11: embryonal carcinoma (5), adult teratoma (2), malignant teratoma (2), seminoma (1), metastatic malignant lymphoma (1)], and scrotal hemangioma (1). (13 refs)

- 79-2375 Menstrual History and Breast Cancer.** (Bul) Todorov, V. (Surgical Clinic, Res. Inst. Oncology, Sofia, Bulgaria). *Vopr Onkol* 15(4): 171-174; 1979.

To determine whether age at menarche is a risk factor for breast cancer, the menstrual histories of 564 women with a histologically confirmed diagnosis of breast cancer and 1,136 healthy women (controls) were analyzed. It was found that 11.5% of the patients began to menstruate at age of 12, compared with 1.9% of the controls. Late onset of menarche (after 17 yr) was found in 1.4% of the patients, compared with 4.7% of the controls. Prolonged (> 35 yr) active function of the ovaries was recorded in 57% of the patients vs 40.0% of the controls. (24 refs)

- 79-2376 Demographic Investigation of Mammary Carcinoma in Northern Sweden.** (Eng) Larsson, L. G. (Center Oncology, Univ. Hosp., S-901 85 Umea, Sweden); Sandstrom, A.; Cumberbatch, J.; Johnsson, M. *Acta Radiol [Oncol]* (Stockh) 17(6): 497-509; 1978.

The age-standardized incidence rates for female breast carcinoma during 1959-1971 were calculated for the three northernmost counties in Sweden and their municipalities. The age-adjusted incidence rate for the entire region was 58.8 compared with 76.3/100,000 for the whole of Sweden. However, very great variations existed between different municipalities. In 11/35 municipalities, the rates differed significantly from the incidence for the entire region, and in 9 of these municipalities the deviation was towards a lower incidence. Age-specific incidence curves were compared for high-incidence, medium-incidence, and low-incidence municipalities. All curves showed a peculiar hook around the age of menopause. For the low-incidence municipalities a bimodal curve was obtained. The most marked difference between low-incidence and high-incidence municipalities concerned the postmenopausal age. For the period 1959-1971, the crude incidence increased by 3%/yr and the age-adjusted incidence increased by 1.5%/yr, both in the whole of Sweden and in the three counties. Therefore, about half of the increase in incidence rate could be explained by the changing age distribution. Other factors must account for the remainder of the increase. (31 refs)

- 79-2377 Ovarian Cancer. Incidence and Case-Control**

79-2377 Study. (Eng) Annegers, J. F. (Section Medical Statistics, Mayo Clinic, 200 First St. S.W., Rochester, MN, 55901); Strom, H.; Decker, D. G.; Dockerty, M. B.; O'Fallon, W. M. *Cancer* 43(2): 723-729; 1979.

The incidence of ovarian cancer in Rochester, Minnesota, during 1935-1974 was determined, and potential risk factors for epithelial ovarian cancer were evaluated based on 116 ovarian cancer patients and 464 matched controls. The incidences of ovarian cancer, adjusted for age and population at risk, were 25.0, 22.9, and 17.8 per 100,000 during 1945-1954, 1955-1964, and 1965-1974, respectively. The age-adjusted incidence rate was 22.6/100,000 during 1935-1944. The incidence rates rose sharply until approx age 60, then leveled off. There was no apparent association between the incidence of breast and ovarian cancer. Among the 116 epithelial ovarian cancer patients and 464 controls, nulliparity, with a relative risk of 1.8, was the only significant risk factor for ovarian cancer. Age at menopause, obesity, hypertension, prior pelvic radiation, and prior exogenous estrogen usage were not significant risk factors. The ovarian cancer patients had a significantly lower frequency of prior hysterectomy and of unilateral oophorectomy than the controls. Thus, the available data seem to support previous findings that women who have had a hysterectomy but retain at least one intact ovary are at lower risk of subsequent ovarian cancer than those who have not had a hysterectomy. (21 refs)

79-2378 Epidemiology of Carcinoma In Situ of the Cervix Uteri. (Eng) Sachs, H. (Universitäts-Frauenklinik, D-6650 Hamburg, W. Germany). In: *Cervical Pathology and Colposcopy. Selected Papers from the Second World Congress of Cervical Pathology and Colposcopy held in Graz, Austria, 15-18 October 1975.* Burghardt, E.; Holzer, E.; Jordan, J. A., eds. (Stuttgart: Georg Thieme Publishers): 146 pp.; 119-122; 1978.

A review of epidemiological studies of carcinoma in situ of the cervix uteri in West Germany shows a higher percentage of cytologically detected carcinoma in situ cases than might be expected based on the number of women participating in routine cancer detection programs. This rate was nearly 80% in Sudwürttemberg-Hohenzollern for the year 1972 and 45% in the Saarland for the year 1973. Carcinoma in situ of the cervix uteri is predominantly detected by routine mass screening in women under the age of 50. A review of 10,425 cases of carcinoma in situ of the cervix uteri observed throughout the world in women under the age of 30 yr shows that the incidence of this disease in this age group ranges from 9.1% to 17.6%. It is suggested that women, particularly older women, should be encouraged to participate in routine mass screening and that women with specific risk factors for cervical cancer should be identified and persuaded to have routine gynecologic examinations. (11 refs)

79-2379 Relationship Between the Age of the Beginning of Sexual Activity and Socio-Economic Status in the Incidence of Carcinoma of the Uterine Cervix. (Eng) de Almeida, A. C. (Catholic Medical Sch., Porto Alegre, Brazil); Callegari, T. R. In: *Prevention and Detection of Cancer. Part II. Detection. Vol. 1. High Risk Markers. Detection Methods and Management.* Nieburgs, H. E., ed. (New York: Marcel Dekker): 1299 pp.; pp. 65-74; 1978.

The relationships between age at the beginning of sexual activity, socioeconomic status (SES), and cervical cancer were studied in 3,920 Brazilian women who had undergone cytologic and/or colposcopic examination of the uterine cervix. The incidence of cervical cancer was 83/3,920 total study population; 46/1,667 women of low SES and 37/2,253 women of high SES. Significantly more women of low SES (55.1%) engaged in sexual activity before 20 yr of age than did women of high SES (44.9%). The incidence of cervical cancer was significantly higher among women of low SES who began sexual activity before the age of 20 (74.5%) than among those of low SES who began sexual activity after the age of 20. There was no significant difference in the incidence of cervical cancer when related to age of first sexual activity in women of high SES. (16 refs)

79-2380 Epidemiology--Some New Aspects on the Prevention of Cervical Cancer. (Eng) Pauli, H. K. (Chefarzt der Geburtshilflich, Gynakologischen Abteilung am Krankenhaus, Elim, Hohe Weide 17, D-2000 Hamburg 19, W. Germany). In: *Cervical Pathology and Colposcopy. Selected Papers from the Second World Congress of Cervical Pathology and Colposcopy held in Graz, Austria, 15-18 October 1975.* Burghardt, E.; Holzer, E.; Jordan, J. A., eds. (Stuttgart: Georg Thieme Publishers): 146 pp.; 111-119; 1978.

Social characteristics were analyzed among 756 women in West Germany who were suffering from squamous carcinoma of the cervix or its preliminary stages. The incidence of carcinoma of the cervix was found to be more frequent when the following social factors appeared: no or few social contacts, no bathroom, coitus during teenage years, two or more intimate partners, two or more marriages, pregnancies, births, and birth of first child during adolescence. Women with none or only one of these factors were classified as low risk, women with two or three as medium risk, and women with more than three factors as high risk. The proportion of women with carcinoma of the cervix increased from 4.4% for low risk to 9.4% for medium risk to 15.8% for high risk. The number of women with a high number of social factors that inhibited attendance for gynecological screening increased according to the number of risk factors. (27 refs)

79-2381 Field Trials in Cervical Cancer in the R.S.A. (Eng) Muller, C. J. (Dept. Radiology, Univ. Stellenbosch, Stellenbosch, South Africa). In: *Prevention and*

Detection of Cancer. Part II. Detection. Vol. 1. High Risk Markers. Detection Methods and Management. Nieburgs, H. E., ed. (New York: Marcel Dekker): 1299 pp.; 57-63; 1978.

Preliminary results of a cervical cancer screening program among South Africans are presented. Early cases were detected by Papanicolaou smears. The results showed an inverse correlation between the incidence of cervical cancer and socioeconomic group. (11 refs)

79-2382 Cancer Epidemiology. A Continuing Series on Different Sites, Based on the New South Wales Data. Series No 6: Cancer of the Prostate and Bladder in NSW. (Eng) Ford, J. (Central Cancer Registry, Health Commission of NSW, GPO Box 4235, Sydney, NSW 2001). *Cancer Forum* (12): 475-478; 1977.

Data collected by the New South Wales Central Cancer Registry revealed that cancer of the prostate ranks second to lung cancer among the leading cancers of men in this state. In 1972, there were 535 new cases, constituting 10% of all new male cancer cases. The incidence rate rises sharply at age 60 and continues to increase with increasing age. There were 434 deaths from cancer of the prostate in 1972, making this the second leading cause of death from cancer (after lung cancer) in men. Cancer of the bladder was the sixth leading primary cancer among men in New South Wales. The total number of new cases was 292 (6% of all new male cancers), and the incidence rate was 12.7%. The male:female ratio of incidence rates for bladder cancer was 2.89:1. (no refs)

79-2383 Occupational Cancer in Men Exposed to Dust and Other Environmental Hazards. (Eng) Bross, I. D. (Roswell Park Memorial Inst., Buffalo, NY); Viadana, E.; Houten, L. *Arch Environ Health* 33(6): 300-307; 1978.

Data on a series of 14,000 cancer patients admitted to one institution between 1956 and 1965 and for whom a detailed epidemiological schedule involving occupational history and

> 75 other factors was taken prior to diagnosis were analyzed for occupational cancer risks. A number of relationships were found between occupations in which dust exposure would be suspected and cancers at particular sites. The risk of melanoma was the most widespread, being significantly elevated in five occupational groups (blacksmiths, excavators, laborers in paper manufacturing, millwrights, and roofers). The risk of stomach cancer was significantly elevated in three occupational groups (millwrights, operatives employed in the textile industry, and shoemakers), as was the risk of pancreatic cancer (laborers in miscellaneous manufacturing, operatives in paper manufacturing, and shoemakers) and cancer of the nose (brickmasons, operatives employed in the textile industry, and shoemakers). The risk of cancer of the buccal-pharyngeal cavity (shoemakers), esophagus (brickmasons, laborers in lumber industry), prostate (blacksmiths, dairy farmers), kidney (brickmasons, roofers), and bladder (dairy farmers) was significantly elevated in at least one occupational group. The findings were not significantly altered by including smoking habits or ethnic background in the analysis. (12 refs)

79-2384 A Nonlinear Stochastic Model for Optimal Estimation of Causative Factors in Cancer. (Eng)

Prasad, T. (Univ. Waterloo, Waterloo, Ontario, Canada N2L 3G1); Ibidapo-Obe, O.; Prasad, S. In: *Prevention and Detection of Cancer. Part II. Detection. Vol. 1. High Risk Markers. Detection Methods and Management*. Nieburgs, H. E., ed. (New York: Marcel Dekker): 1299 pp.; 1287-1296; 1978.

A model corresponding to the Ito-Doob nonlinear stochastic integral equations is proposed for the in vitro estimation of the causative factors for cancerous growth. The model depicts a simplified version of the essential biological concepts that underlie a cancerous state. Realistic mathematical algorithms yielding conceptually similar and explicit solution schemes and based on the innovations concept and theory of martingales are outlined. The algorithm may also provide a basis for cancer chemotherapy and compact and precise mathematicobiophysical representations for other physiological problems. The approach is interdisciplinary in character, and its utilization would depend on effective coordination between researchers from diverse disciplines. (24 refs)

79-2385 Models of Cell Surface Events During Normal and Transformed Human Cellular Adhesion In Vitro. (Eng)

Rajaraman, R. (Dept. Microbiology, Faculty Medicine, Dalhousie Univ., Halifax, Nova Scotia, Canada); Fox, R. A.; MacSween, J. M. *Ann NY Acad Sci* 312: 441-443; 1978.

It is hypothesized that patching, capping, endocytosis, and cellular locomotion are manifestations of a single process: the cell discarding foreign and unwanted materials. A molecular model of normal and neoplastic cellular adhesion in the presence and absence of serum is proposed based on the interpretation that capping is caused by abortive adhesion and does not result in locomotion. In this model, normal, but not transformed, cells have adhesion sites (A molecules) on their surface that bind to B molecules in serum. Blockage of A molecules on normal cells by binding of free B molecules is cleared by capping, whereas binding of A molecules with substratum-bound B molecules results in cellular adhesion. Transformed cells may recruit A molecules from serum to attain deformability and spreading. These cells may be defective in capping surface-bound ligands. Thus, the degree of dependence on serum for deformation and spreading may be determined by the rate at which the cell can synthesize endogenously and/or recruit exogenously A molecules. The major differences between normal and transformed cellular

adhesion and spreading appear to be the lack of adhesion sites and the lower rate of formation of adhesion sites at the active edges in the latter. (22 refs)

79-2386 Independence of Normal Phenotypic Properties and Cell Surface Receptor Mobility in Variant Cell Lines. (Eng)

Williams, R. E. (Dept. Microbiology, Molecular Biology Inst., Univ. California, Los Angeles, CA, 90024); Linsley, P. S.; Rittenhouse, H. G.; Fox, C. F.; Boone, C. W. *J Supramol Struct* 9(2): 147-156; 1978.

Three classes of variant cell lines derived from the transformed LM line were compared with the parental cells with respect to several characteristics commonly associated with malignant transformation. The LM cell line has evolved over a 35-yr period from a methylcholanthrene-treated culture of L cells into a line adapted for growth in serum-free medium. In contrast to LM, all variant lines showed an obligate serum requirement for growth and displayed phenotypic properties consistent with an increased anchorage dependence for growth. All variants were at least slightly tumorigenic in male C3H/NIH mice, although the tumors induced by the higher dilutions of variant cells tended to develop more slowly than those induced by LM. The variants were less agglutinable by concanavalin A (Con A) than was LM, but the Con A-binding sites of all variants and the parental line had identical tendencies to cluster in response to lectin treatment. Thus, the apparent mobility of Con A-binding sites is not a reliable attribute of the transformed cell, since it is easily uncoupled from other, more established indicators of transformation. 79-2387 Transformation-sensitive Cell Surface Protein: Isolation, Characterization, and Role in Cellular Morphology and Adhesion. (Eng)

Yamada, K. M. (Lab. Molecular Biology, NCI, Bethesda, MD, 20014); Olden, K.; Pastan, I. *Ann NY Acad Sci* 312: 256-277; 1978.

The structure, composition, function, mobility, and regulation of a transformation-sensitive glycoprotein known as cell-surface protein (CSP) or LETS (large, external, transformation-sensitive) protein were investigated with purified preparations from chick embryo fibroblasts (CEF). CSP is an adhesive protein that increases cell-cell and cell-substratum adhesiveness. Transformation of CEF results in decreased quantities of CSP due primarily to a fivefold reduction of CSP

biosynthesis, although increased proteolytic degradation and shedding from the cell surface also contribute. The decreased biosynthesis is apparently due to a fivefold reduction in translatable messenger RNA for CSP. Reconstitution of isolated purified CSP on 14 transformed chicken, mouse, rat, hamster, and human cell lines resulted in reversion to a more normal fibroblastic morphology, adhesiveness, cell-surface architecture, microfilament bundle organization, motility, and alignment at confluence. CSP did not restore growth control. The effects of CSP appear to be due to increased cell-substratum adhesion plus altered cell-cell interactions. Untransformed CEF treated with affinity-purified antibodies to CSP develop the rounded morphology characteristic of many transformed cells that are CSP-deficient. CSP is found primarily in fibrillar aggregates on the cell surface. Isolated CSP consists of highly asymmetric disulfide-linked dimers and multimers. The interchain disulfide bridges are confined to a short terminal fragment that is readily removed by trypsin. CSP and cold-insoluble globulin have similar compositions but differ in solubility and amino termini. CSP contains primarily asparagine-linked oligosaccharides that appear responsible for the concanavalin A receptor activity of CSP. Inhibition of CSP glycosylation by tunicamycin results in decreased CSP due to marked increases in its degradation rate, without inhibition of synthesis or secretion. Studies of CSP have provided insight into cellular adhesion, morphology, and social interaction and provide an approach to analyze the dynamics and regulation of protein synthesis, glycosylation, secretion, and turnover. (47 refs)

- 79-2388 Subunit Structure of Surface and Shed Large, External, Transformation-sensitive Protein of Chick Embryo Fibroblasts.** (Eng) McConnell, M. R. (Dept. Pharmacology, Harvard Medical Sch., Boston, MA, 02115); Blumberg, P. M. *Ann NY Acad Sci* 312: 418-419; 1978.

For the chick fibroblast system, quantitation after lactoperoxidase-catalyzed iodination indicated that 21.3% of total surface LETS (large, external, transformation-sensitive) protein was present as the dimer and 77.4% as the oligomer. Similar studies of shed LETS protein indicated that its subunit structure closely resembles that of surface LETS protein. Apparently, the LETS protein dimer is as stable in its attachment to the cell surface as the oligomeric form, as both seem to be released from the cell surface into the medium at similar rates. (4 refs)

- 79-2389 Chemical Composition, Gross Structure, and Organization of Transformation-sensitive Glycoproteins.** (Eng) Carter, W. G. (Biochemical Oncology, Fred Hutchinson Cancer Res. Center, Univ. Washington, Seattle, WA, 98104); Fukuda, M.; Lingwood, C.; Hakomori, S. *Ann NY Acad Sci* 312: 160-177; 1978.

Three classes of transformation-sensitive, surface-labeled

glycoproteins (gp) were detected in studies of the galactoproteins (Gap) of hamster NIL and NILpy (polyoma virus-transformed) cells. Gap a, a gp with a subunit mol wt of 230,000 (230K), was deleted in transformed cells and showed high sensitivity to exogenous treatment of cells with trypsin. In contrast, increased amount of label was found in a 130K gp (Gap b) in NILpy cells. The Gap b fraction of NILpy cells also contained a gp (Gap bT) whose mobility on gel electrophoresis was faster than that of normal Gap b. A new gp with a subunit mol wt of 170K was found to be a transformation-sensitive but protease-resistant gp. This gp was also deleted in transformed cells. The chemical composition, gross structure, and organization of these gp are presented, and their sequential extraction is illustrated. Most of the membrane and cytoplasmic proteins were extracted by sequential treatment of cells with sucrose-ATP-EDTA, followed by the zwitterionic detergent Empigen BB, whereas part of the cytoskeletal proteins, including an "actinlike protein," and essentially all Gap a remained unextracted. Subsequent urea extraction solubilized an actinlike protein that was copurified with Gap a upon affinity chromatography with a *Ricinus communis*-polyacrylylhydrazidoagarose column. A serum gp immunologically identical to Gap a has been detected in conditioned culture media; presumably, it is shed from the cells as a soluble form of Gap a (released-form Gap a). Both Gap a and gp 170K appear to be associated with particular cytoskeletal proteins. A possible association of gp 170K with an intermediate filament protein is suggested by affinity copurification and coprecipitation. Some data also suggest that Gap a and actin are associated. An interaction between membrane glycolipids and proteins extracted from the same cells is postulated. This glycolipid-ektoprotein interaction could be a molecular basis of intercellular interaction. (39 refs)

- 79-2390 A Large Glycoprotein Lost from the Surfaces of Transformed Cells.** (Eng) Hynes, R. O. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139); Ali, I. U.; Destree, A. T.; Mautner, V.; Perkins, M. E.; Senger, D. R.; Wagner, D. D.; Smith, K. K. *Ann NY Acad Sci* 312: 317-342; 1978.

Studies of the structure and functions of a large, external, transformation-sensitive (LETS) protein that is lost or greatly reduced on the surface of transformed cells are presented. Alterations in LETS protein levels at the cell surface occur upon transformation and, in normal cells, in response to growth stimulation and during the cell cycle. There appear to be differences however, between the situation in transformed cells (lower rate of synthesis, higher rate of turnover) and growing normal cells (lower rate of synthesis, no evidence for increased turnover). Readdition of LETS protein to transformed cells causes increased attachment, stronger adhesion, and greater spreading and elongation of the cells. The elevated numbers of microvilli and ruffles characteristic of many transformed cells can be reduced by the addition of LETS protein, and microfilament bundles characteristic of normal

cells can be restored. The locations of LETS protein beneath spreading and migrating cells are consistent with the hypothesis that LETS plays a role in cellular spreading and movement. It is also possible that LETS protein is involved in cell-cell adhesion. Cold-insoluble globulin (CIg) and LETS protein are closely related antigenically and structurally, but CIg is two to three times less active in promoting the attachment of transformed cells to plastic dishes. It can, however, perform similar functions regarding the adhesion of platelets. (79 refs)

79-2391 Fibronectin and the Pericellular Matrix of Normal and Transformed Adherent Cells. (Eng)

Vaheri, A. (Dept. Virology, Univ. Helsinki, 00290 Helsinki 29, Finland); Alitalo, K.; Hedman, K.; Keski-Oja, J.; Kurkinen, M.; Wartiovaara, J. *Ann NY Acad Sci* 312: 343-353; 1978.

The organization and composition of insoluble fibronectin (FN)-containing structures in layers of adherent cells are reviewed. FN appears to be a major component of a pericellular (PC) matrix that can be regarded as an in vitro equivalent of the basal laminae and connective tissue matrix. The significance of the PC matrix to normal cells and of the loss of the matrix to transformed cells is considered. PC FN is located predominantly in fibrillar structures that often mediate distant cell-cell and cell-substratum contacts. A small proportion is closely associated with the plasma membrane. In the matrix, FN is partially disulfide-bonded into complexes. Plasma transglutaminase, activated by thrombin, also cross-links external FN into high-mol-wt covalent complexes. In cultures of normal fibroblasts, PC FN displays an extensive codistribution with (pro)collagens types I and III. Transformed adherent cells show a decreased formation of the FN-collagen matrix. In normal chick embryo fibroblasts there is a dense meshwork of fibrillar matrix in which both FN and procollagen type I are present. In cultures of fibroblasts transformed with Rous sarcoma virus, little or no PC FN or procollagen is detected. The loss of the PC FN-collagen matrix during transformation may be due to decreased synthesis of the matrix components and decreased binding of these components to the cell layers. The PC matrix structure was isolated by the sequential exposure of cells to sodium deoxycholate and hypotonic buffers in the presence of protease inhibitors. Human sarcoma cells seeded on this matrix spread rapidly and assume the morphology characteristic of normal fibroblasts. These results suggest that the FN-collagen matrix in vitro may provide a model system for studies of the functions of the basal laminae and connective tissue matrix. (45 refs)

79-2392 Modulation of Cell Surface Glycocalyx: Studies on Large, External, Transformation-sensitive Protein. (Eng) Chen, L. B. (Sidney Farber Cancer Inst., Harvard Medical Sch., Boston, MA, 02115); Burridge, K.; Mur-

ray, A.; Walsh, M. L.; Copple, C. D.; Bushnell, A.; McDougall, J. K.; Gallimore, P. H. *Ann NY Acad Sci* 312: 366-381; 1978.

Studies of the large, external, transformation-sensitive (LETS) protein and its relation to cold insoluble globulin (CIg), to oncogenicity, and to collagen are discussed. LETS and CIg are similar antigenically and in their amino acid compositions. However, the N-terminal amino acids and sialic acid compositions are different, CIg migrates slightly faster than LETS protein on sodium dodecyl sulfate-polyacrylamide gels, and purified human CIg does not restore normal morphological features in transformed chick cells but chick LETS protein does. In virally transformed cell lines there is a correlation between an increase in tumorigenicity in vivo and a decrease in the percentage of cells that express LETS protein on cell-cell contact. In > 100 normal cell lines studied, four categories of LETS protein distribution were detected: (1) in the cell-substratum contact area; (2) in the cell-substratum and cell-cell contact areas; (3) in the cell-cell contact area; and (4) in some of the cell-cell contact areas. Electron microscopic studies of chick embryo fibroblasts indicate that the fibrillar structures that contain LETS protein are composed of numerous fine fibers (40-60 Å), many of which are clustered together. These studies also indicate that LETS protein distributes as a three-dimensional matrix in confluent culture and that the secretion and early fibrillogenesis of LETS protein and collagen are distinct but that in the later stages of matrix formation, they may interact in certain cell types. (39 refs)

79-2393 Differences in the Ultrastructural Localization of Fibronectin on Normal and Transformed Cells. (Eng) Furcht, L. T. (Dept. Lab. Medicine and Pathology, Univ. Minnesota Medical Sch., Minneapolis, MN, 55455); Mosher, D. F.; Wendelschafer-Crabb, G. *Ann NY Acad Sci* 312: 426-431; 1978.

Studies of fibronectin (FN) organization on normal and transformed human fibroblasts (FB) using the peroxidase-antiperoxidase method are reviewed. Human FB from low-density cell populations lacks any significant amount of extracellular components. With increasing density and cellular contacts, an extensive extracellular filamentous matrix (EFM) develops that is most pronounced at cell-cell and cell-substratum contact sites. Simian virus 40 (SV40)-transformed human FB fails to develop the EFM. Two patterns of FN localization were observed in contacted human FB: an intense reaction to the EFM and a diffuse nonstructured binding to the cell membrane. In SV40-transformed human FB, FN was detected in a patchy, diffuse, membrane-associated form that was decreased in intensity relative to the diffuse form seen in normal human FB. The EFM can be disrupted by mild trypsin digestion, but it is little affected by collagenase. SV40-transformed human cells produce much more FN than normal cells. Therefore, the fundamental perturbation that occurs on transformation may be a failure to

organize FN into an EFM. The presence or absence of an EFM composed of FN may be involved in the phenotypic characteristics of normal and transformed cells. Whether an EFM is formed in transformed cells and then degraded or is never formed is being investigated. (12 refs)

- 79-2394 Restriction and Modification Enzymes and Their Recognition Sequences.** (Eng) Roberts, R. J. (Cold Spring Harbor Lab., P.O. Box 100, Cold Spring Harbor, NY, 11524). *Gene* 4(3): 183-193; 1978.

A table is presented of 177 endonucleases known to cleave DNA at a specific sequence. Also listed are the microorganism from which an enzyme was isolated, the microorganism's source, the sequence recognized by the enzyme, the number of cleavage sites, and appropriate references. (86 refs)

- 79-2395 Cellular Transglutaminase, Growth, and Transformation.** (Eng) Birckbichler, P. J. (Biomedical Div., Samuel Roberts Noble Foundation, Inc., Ardmore, OK, 73401); Patterson, M. K. *Ann NY Acad Sci* 312: 354-365; 1978.

Transglutaminase (TGase) activity and its possible relationship to transformation were studied in cultures derived from human embryonic lung, strain WI-38, and a simian virus 40 (SV40)-transformed counterpart, WI-38 VA13A. TGase activity was higher in the normal than in the transformed lung cells and in several other paired cell systems (eg, rat liver and malignant primary and transplanted hepatoma). The enzymatic reaction product, ϵ -(γ -glutamyl)lysine, was present in greater amounts in WI-38 than in WI-38 VA12A cells. Both enzymatic activity and immunofluorescent staining with rabbit anti-TGase were greater in confluent, nongrowing normal cells. TGase activity could be increased by incubation of cells with low levels of some proteases (eg, trypsin). In WI-38 homogenates, there appeared to be an inverse relationship between growth of the cells and enzymatic activity. During rapid proliferation, enzymatic activity was low. As proliferation ceased, TGase activity increased and continued to rise for several days after confluence. It is postulated that the low enzymatic activity in transformed cell systems reflects the presence of a rapidly proliferating population. There are several similarities between TGase and fibronectin (FN): normal lung fibroblasts have higher TGase activity and bind FN; TGase activity and cell-surface FN in these cells parallel one another; proteases that cleave FN activate TGase and the time course is similar for these two phenomena. FN serves as a substrate for TGase. These findings indicate that there is a close relationship between TGase and FN. (32 refs)

- 79-2396 Flow Microfluorometric Identification of Liver Cells with Elevated Gamma-Glutamyltranspep-**

tidase Activity after Carcinogen Exposure. (Eng) Vanderlaan, M. (Biomedical Sciences Div., Lawrence Livermore Lab., Univ. California, Livermore, CA, 94550); Cutter, C.; Dolbeare, F. *J Histochem Cytochem* 27(1): 114-119; 1979.

A fluorometric cytochemical assay for γ -glutamyltranspeptidase (γ -GT) activity was developed. γ -Glutamyl-4-methoxy-2-naphthylamide was used as substrate, and the released methoxynaphthylamide was coupled with 5-nitrosalicylaldehyde to form a yellow fluorescent crystalline product within the cells. Single cell suspensions were obtained by collagenase perfusion of livers from female Simonson albino rats that had undergone two-thirds partial hepatectomy followed in some cases by a single ip injection of diethylnitrosamine (DEN, 13 mg/kg) 24 hr later. Cultured hepatoma HTC-B1 cells were used as a source of monodisperse cells for the development of flow cytometric techniques. Fluorescence (γ -GT activity) was extensive in the HTC cells, but most hepatocytes from untreated and DEN-treated hepatectomized rats were negative for γ -GT. The livers of both DEN-treated and untreated rats contained some cells that were positive for γ -GT; these subpopulations could be quantitated and sorted by flow cytometry. Five weeks after DEN treatment, the percentage of γ -GT-positive cells in the livers from DEN-treated rats was 20-fold higher than that in the livers from untreated rats. Fluorescence sorting of γ -GT-positive cells may be useful for studies of early neoplastic events in a variety of organs. (25 refs)

- 79-2397 Superoxide Dismutase in Normal and Malignant Tissues in Different Species.** (Eng) Van Balgooy, J. N. (Div. Neurosciences, City of Hope Natl. Medical Center, Duarte, CA, 91010); Roberts, E. *Comp Biochem Physiol B* 62B(3): 263-268; 1979.

Superoxide dismutase (SOD) distributions in different species were investigated electrophoretically, and isoenzyme patterns in normal and malignant tissues were compared. Brain samples from rat, mouse, guinea pig, hamster, rabbit, frog, and fish contained similar SOD activities [13.0-19.0 units (U)/mg]. Lower activities were found in malignant hamster embryo fibroblasts (8.0-10.0 U/mg and crayfish muscle (4.6-6.2 U/mg), and the highest levels were found in *Escherichia coli* (19.2 U/mg). The isoenzyme patterns differed in tissues from different species. Rat brain contained little slow-moving (Mn-containing, mitochondrial) SOD, and all tissues except crayfish and *E. coli* contained a considerable amount of cyanide-sensitive SOD. In rat brain, the hypothalamus had the highest SOD activity, the cortex the lowest. Total brain SOD activity did not differ with age in mice aged 1 day to adult, but slow-moving SOD increased with age. In general, malignant tissues appeared to have lower SOD activities than normal tissue, although the values for leukemias 5FU and P388 were in the range of those for normal lung and brain. The distribution of the Cu-containing SOD isoenzymes in tumor tissue was similar to that of normal host

tissue, but the Mn-containing SOD was barely detectable in tumor cells. (25 refs)

79-2398 Teratoma Induction in Mice and Rats in Relation to the Age of the Visceral Yolk Sac. (Eng)

Sobis, H. (Rega Inst. Medical Res., Univ. Leuven, B-3000 Leuven, Belgium); Vandeputte, M. *Eur J Cancer* 15(2): 143-151; 1979.

The morphological and biological characteristics of yolk sac-derived teratomas were studied in C3H and C57Bl mice and in R and BN rats. The yolk sacs were pulled outside the uterine horns during fetectomy (Fe-x) at varying times during gestation, and they were fixed and examined 2 days later. Mouse yolk sacs examined 2 days after Fe-x on day 11 were similar to those observed in utero on the day of Fe-x, whereas those pulled outside the uterus on day 13 and examined on day 15 showed flattened epithelial cells, reduced mesenchymal cell numbers, and thickened basement membranes. Mouse yolk sacs pulled out on day 15 showed only necrotic cells and a very thick basement membrane. After Fe-x, rat yolk sacs were similar in morphology to those observed in the earlier stages of pregnancy in mice. Treatment of pregnant mice with busulfan (BS: 3 mg/100 g ip on gestation day 9) nearly eliminated the germ cells from the gonads of the newborn offspring. All untreated and BS-treated mice fetectomized on day 11 of pregnancy developed one to four teratomas per uterine horn. The tumors showed endodermal cysts, gut formation, pancreas, epidermal cysts with skin components such as hair and sebaceous glands, cartilage, bone, and bone marrow. Skeletal muscle, nervous tissue, bronchiolar epithelium, lymphoid tissue, and liver were also seen occasionally. The morphology of the tumors varied with the time of Fe-x. The tumors observed in rats were similar to those observed in mice. The data indicate that the capacity of the visceral yolk sac to differentiate into various adult tissues is common to most species of rodents and that benign teratomas develop from the fetal membranes and not from germ cells or embryonal cells. 79-2399 Hematopoietic Stem-Cell Seeding of a Cellular Matrix: A Principle of Initiation and Regeneration of Hematopoiesis. (Eng) Flidner, T. M. (Abteilung für Klinische Physiologie, Universität Ulm, Ulm, W. Germany); Calvo, W. *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 757-773; 1978.

Evidence is presented for the hypothesis that efficient hematopoietic cell differentiation and blood cell production require an interaction between a stem cell population and a suitable cellular matrix. Studies of the human embryo indicated that bone marrow development takes 15 wk. In each skeletal part, the sequence of events leading to the establishment first of a matrix and secondly of hematopoietic parenchyma was the same. During a 1- to 2-wk period, the bone

marrow consisted of a matrix but not of hematopoietic parenchyma. Stem cell seeding of this matrix appeared to be a process having several stages. Electron microscope studies of the bone marrow of dogs that had been rendered aplastic by lethal whole-body x-irradiation indicated that circulating stem cells leave the blood and enter the extravascular space to initiate colonization of the marrow. The kinetic response of matrix cells to the seeding of normal and leukemic stem cells was studied in rats. Under normal circumstances, the cellular matrix had a slow renewal rate that could be measured by the (³H)-thymidine labeling method. The renewal rate was not altered by emigration or immigration of stem cells. The mechanical destruction of parts of the cellular matrix, however, resulted in the proliferation of the remaining cells to restore the matrix to its original size. The immigration of leukemic stem cells destroyed the endothelial and reticular matrix of effective hematopoiesis, and apparently inhibited the regeneration of the matrix and the replication of normal hematopoietic stem cells. 79-2400 Cellular and Architectural Factors Influencing the Proliferation of Hematopoietic Stem Cells.

(Eng) Lord, B. I. (Paterson Labs., Christie Hosp. and Holt Radium Inst., Withington, Manchester M20 9BX, England). *Cold Spring Harbor Conf Cell Proliferation* Vol. 5(Book B), 994 pp.; 775-788; 1978.

The organization of stem cells within the bone marrow spaces was examined, and the relationship between bone and the proliferation of stem cells was studied. Marrow from the cylindrical part of the mouse femoral shaft was fractionated into axial and marginal zones of varying sizes, and the cell populations obtained were assayed for spleen colony-forming cells (CFU-S) and for committed granulocyte precursor cells (CFU-C). CFU-S levels were considerably higher (45/10⁵ cells) in the vicinity of the bone surfaces than in the center of the bone (15/10⁵ cells). CFU-C proliferated rapidly in all regions of the marrow, but CFU-S proliferated in the vicinity of the bone but not in the center. Only 6% of bone marrow CFU-S were killed by a single in vivo dose of 1 mCi (³H)-thymidine given 30 min earlier, compared with 60% of bone CFU-S. At 5 days, <10% of bone-derived CFU-S and 60% of marrow-derived CFU-S survived. One fraction (fraction IV) of normal bone marrow extracts specifically inhibited the proliferation of CFU-S. One of the fractions from regenerating bone marrow (RBME-III) stimulated resting CFU-S from normal bone marrow, increasing the proportion in the S phase of DNA synthesis from 9% to 37%. This property was not shared by the corresponding fraction from normal bone marrow, but fraction III from normal bone stimulated CFU-S proliferation in the same way as did RBME-III. It is suggested that the proliferation stimulatory factor found in bone and regenerating bone marrow and the proliferation inhibitory factor found in normal bone marrow act competitively to adjust the level of CFU-S proliferation to suit the animals' requirements. LIBRARY U. OF I. URBANA - CHAMPAIGN

Subject Index

Abnormalities

- Radiation, Ionizing
 - In Utero Exposure, Review, 79-1832
- 4,4'-Stilbenediol, α,α' -Diethyl-
 - Genital Tract, 79-2092
 - Hypothalamo-Hypophyseal System, 79-2092
 - In Utero Exposure, 79-2092

Acetamide

- Diethylamine
 - Air Pollution, 79-2052
- Triethylamine
 - Air Pollution, 79-2052
- Virus, Rauscher Murine Leukemia
 - Erythropoiesis, 79-2158

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl

- Acetamide, *N*-Fluoren-2-yl-
 - Carcinogenic Metabolite, 79-1944
- Cell Transformation, Neoplastic
 - Ouabain Resistance, 79-1995
- Cells, Cultured
 - DNA Adducts, 79-1946
- DNA Adducts
 - Radioimmunoassay, 79-1946
- Escherichia coli*
 - DNA Repair, 79-1945
- Fibroblasts
 - Ouabain Resistance, 79-1995
- Guanosine, 2'-Deoxy-
 - DNA Adducts, 79-1946
- Hydrolysis
 - DNA, Binding, 79-1944
- Lymphocytes
 - DNA Replication, 79-1907
- Virus, Epstein-Barr
 - Virus Activation, 79-2032

Acetamide, *N*-(2-Chloroethyl)-*N*-nitroso-

- Ames Test
 - Mutagenic Activity, 79-1973

Acetamide, *N*-Fluoren-2-yl-

- Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl
 - Carcinogenic Metabolite, 79-1944
- Aldehyde Oxidoreductases
 - Liver, Intestine, Rat, 79-1984
- Ames Test
 - Hepatocyte Nucleus, 79-1947
 - Mutagenic Activity, 79-1947
 - S9 Fraction, 79-1947
- Barbituric Acid, 5-Ethyl-5-phenyl-
 - Metabolism, Liver, 79-1947
- Cholanthrene, 3-Methyl-
 - Metabolism, Liver, 79-1947
- Diethylamine, *N*-Nitroso-
 - Hepatocarcinogenicity, Rat, 79-1966
- DNA Nucleotidyltransferases
 - DNA Replication, 79-1948
 - Hepatocarcinogenesis, 79-1948
 - Liver, Rat, 79-1948
- Dose-Response Study
 - Hepatotoxicity, 79-1950
- Endoplasmic Reticulum
 - Liver, Rat, 79-1950
- Ethionine, *S*-Adenosyl-

Acetamide, *N*-Fluoren-2-yl- (cont'd)

- Liver, Rat, 79-1951
- Glycogen
 - Liver, Rat, 79-1950
- Hepatoma
 - p*-Cresol, 2,6-Di-*tert*-butyl-, 79-1953
 - Dietary Fats, 79-1953
 - Gangliosides, 79-1919
 - Glycolipids, 79-1919
 - Precancerous Conditions, 79-1953
 - Sialic Acid, 79-1919
- Hydrolysis
 - DNA, Binding, 79-1944
- Liver Neoplasms
 - Diethylamine, *N*-Nitroso-, 79-1966
 - Hyperplasia, 79-1966
- Mammary Neoplasms, Experimental
 - Corn Oil, 79-1952
 - Lipids, 79-1952
- Ultrastructural Study
 - Liver, Rat, 79-1950

Acetamide, *N*-Methyl-*N*-nitroso-

- Ames Test
 - Mutagenic Activity, 79-1973

Acetamide, *N*-Nitroso-*N*-propyl-

- Ames Test
 - Mutagenic Activity, 79-1973

Acetamide, Thio-

- RNA Replication
 - Liver, Rat, 79-1971

Acetic Acid, *N*-(4-Acetoxybutylnitrosamino)methyl Ester

- Ames Test
 - Mutagenic Activity, 79-1961

Acetic Acid, *N*-(2-Acetoxyethylnitrosamino)methyl Ester

- Ames Test
 - Mutagenic Activity, 79-1961

Acetic Acid, *N*-(3-Acetoxypropylnitrosamino)methyl Ester

- Ames Test
 - Mutagenic Activity, 79-1961

Acetic Acid, Butylnitrosaminobutyl Ester

- Ames Test
 - Mutagenic Activity, 79-1959

Acetic Acid, Butylnitrosaminomethyl Ester

- Ames Test
 - Mutagenic Activity, 79-1959

Acetic Acid, *N*-(2-Carbomethoxyethylnitrosamino)butyl Ester

- Ames Test
 - Mutagenic Activity, 79-1961

Acetic Acid, *N*-(2-Carbomethoxyethylnitrosamino)methyl Ester

- Ames Test
 - Mutagenic Activity, 79-1961

Acetic Acid, *N*-(Carbomethoxymethylnitrosamino)butyl Ester

- Ames Test
 - Mutagenic Activity, 79-1961

Acetic Acid, *N*-(Carbomethoxymethylnitrosamino)methyl Ester

- Ames Test

- Acetic Acid, *N*-(Carbomethoxymethylnitrosamino)methyl Ester (cont'd)**
 Mutagenic Activity, 79-1961
- Acetic Acid, *N*-(3-Carbomethoxypropylnitrosamino)butyl Ester**
 Ames Test
 Mutagenic Activity, 79-1961
- Acetic Acid, *N*-(3-Carbomethoxypropylnitrosamino)methyl Ester**
 Ames Test
 Mutagenic Activity, 79-1961
- Acetic Acid, ((Carboxymethylimino)bis(ethylenenitrilo))tetra-**
 Citric Acid, Plutonium Salt
 Chelation Therapy, 79-2104
 Liver, Rat, 79-2104
- Acetic Acid, *N*-(Carboxymethylnitrosamino)butyl Ester**
 Ames Test
 Mutagenic Activity, 79-1961
- Acetic Acid, Dichloro-**
 Ames Test
 Mutagenic Activity, 79-1943
- Acetic Acid, Ethylnitrosaminomethyl Ester**
 Ames Test
 Mutagenic Activity, 79-1959
- Acetic Acid, Hydrazide**
 Ames Test
 Mutagenic Activity, 79-1935
- Acetic Acid, 2-Hydroxyethoxy-**
p-Dioxane
 Metabolism, Rat, 79-1981
- Acetic Acid, Mercapto-**
 12-*O*-Tetradecanoylphorbol-13-acetate
 DNA Replication, 79-2045
- Acetic Acid, Methylnitrosaminomethyl Ester**
 Ames Test
 Mutagenic Activity, 79-1959
- Acetic Acid, Propylnitrosaminomethyl Ester**
 Ames Test
 Mutagenic Activity, 79-1959
- Acetic Acid, Thiodi-**
 Ether, Bis(2-chloroethyl)-
 Metabolism, Rat, 79-1916
- Acetohydroxamic Acid, *N*-Fluoren-2-yl-**
 Benzoic Acid, *p*-Hydroxymercuri-
 Lipid Adduct, 79-1949
 Carboxylic Ester Hydrolases
 Ames Test, 79-1949
 Enzyme Activation, 79-1949
 Esterases
 Deacylation, 79-1949
 Fluorene, 2-Nitroso-
 Lipid Adduct, 79-1949
 Microsomes, Liver
 Ames Test, 79-1949
 1-Propanone, 2-Methyl-1,2-di-3-pyridyl-, Tartrate
 Lipid Adduct, 79-1949
- Acetone**
o-Phenylenediamine, 4-Nitro-
 Ames Test, 79-1921
- p*-Acetophenetidide**
 Bladder Neoplasms
- p*-Acetophenetidide (cont'd)**
 Carcinogenic Activity, Rat, 79-2006
 Carcinoma, 79-2006
 Carcinoma, Transitional Cell, 79-2006
 Kidney Neoplasms
 Carcinogenic Activity, Rat, 79-2006
 Carcinoma, 79-2006
 Carcinoma, Transitional Cell, 79-2005, 79-2006
 Case Report, 79-2005
 Nose Neoplasms
 Adenocarcinoma, 79-2006
 Carcinogenic Activity, Rat, 79-2006
 Carcinoma, Epidermoid, 79-2006
 Carcinoma, Transitional Cell, 79-2006
- 2',6'-Acetoxyldide, 2-(Diethylamino)-**
 2-Propanol, 1-(Isopropylamino)-3-(1-naphthoxy)-
 Metabolism, Rat Hepatocytes, 79-2011
- Acetyl Azide, 4-Hydroxy-3-iodo-5-nitrophenyl-**
 Antibody Formation
 Enhancing Factor, 79-2263
- Achlorhydria**
 Gastrointestinal Neoplasms
 Genetics, Review, 79-1875
- Acid Phosphatase**
 Leukemia, Lymphoblastic
 T-Lymphocytes, 79-2301
- Aclacinomycin A**
 Cells, Cultured
 Carcinogenic Activity, 79-1956
- Acrylamide, 2-(2-Furyl)-3-(5-nitro-2-furyl)-**
 Food Contamination
 Carcinogenic Activity, Review, 79-1805
 Mutagenic Activity, Review, 79-1805
 Stomach Neoplasms
 Carcinogenic Activity, Review, 79-1805
- Acrylamide, 2-Phenyl-3-(5-nitro-2-furyl)-**
 Mammary Neoplasms, Experimental
 Carcinogenic Activity, Rat, 79-1987
 Structure-Activity Relationship
 Carcinogenic Activity, Rat, 79-1987
- Acrylic Acid, 3-*p*-Anisoyl-3-bromo-, Sodium Salt**
 Fetal Death
 Genetic Effect, Mouse, 79-1954
- Actin**
 LETS Protein
 Affinity Chromatography, 79-2389
- Actinomycin D**
 Cells, Cultured
 Carcinogenic Activity, 79-1956
 Virus, Herpes Simplex 1
 DNA Replication, 79-2195
 Proteins, 79-2195
 Virus, Herpes Simplex 2
 DNA Replication, 79-2195
 Proteins, 79-2195
- Adenine Nucleotides**
 Benzo(a)pyrene
 Cholanthrene, 3-Methyl-, 79-2060
 Metabolism, Liver, 79-2060
 Thymopoietins
 Lymphocytes, 79-1850
